We report a numerical study of equilibrium phase diagrams and interfacial properties of bulk and confined colloid-polymer mixtures using grand canonical Monte Carlo simulations. Colloidal particles are treated as hard spheres, while the polymer chains are described as soft repulsive spheres. The polymer-polymer, colloid-polymer, and wall-polymer interactions are described by density-dependent potentials derived by Bolhuis and Louis [Macromolecules 35, 1860 (2002)]. We compared our results with those of the Asakura-Oosawa-Vrij model [J. Chem. Phys. 22, 1255 (1954); J. Polym Sci 33, 183 (1958); Pure Appl. Chem. 48, 471 (1976)] that treats the polymers as ideal particles. We find that the number of polymers needed to drive the demixing transition is larger for the interacting polymers, and that the gas-liquid interfacial tension is smaller. When the system is confined between two parallel hard plates, we find capillary condensation. Compared with the Asakura-Oosawa-Vrij model, we find that the excluded volume interactions between the polymers suppress the capillary condensation. In order to induce capillary condensation, smaller undersaturations and smaller plate separations are needed in comparison with ideal polymers.

I. INTRODUCTION

Mixtures of colloids and polymers\textsuperscript{1–3} are simple model systems that have been studied extensively in the past few years. Provided the size and the number of polymers are sufficiently high, such mixtures can phase separate into a colloidal gas phase that is poor in colloids and rich in polymers and a colloidal liquid phase that is rich in colloids and poor in polymers. While it is well established that the interactions between sterically stabilized colloidal particles are well described by the hard sphere potential,\textsuperscript{4} the interactions between the polymers in the mixture can be, in general, very complicated. Nevertheless, if we consider the case of flexible polymer chains in a “good solvent” conditions, we can assume that the excluded volume interactions between the chains are small and that the chains cannot penetrate the colloidal particles. The mechanism behind the demixing transition is then easily explained. In Fig. 1(a), we illustrate the mixture of spherical colloids and polymer chains. Around each colloid, there is a depletion region prohibited to the polymers due to the hard-core interactions. If two colloids approach each other, so that two depletion zones overlap, there is an increase in free volume for the polymer chains, i.e., an increase in entropy. The increase in entropy can be described by an effective attractive interaction between the colloidal particles. A similar depletion mechanism occurs between a hard wall and the colloidal particles. If the polymers do not adsorb at the wall, they are excluded from a region close to the wall. The overlap between the depletion zone at the wall and the depletion zone of one colloid induces an increase in free volume and, hence, in entropy.

One particular simple model for colloid-polymer mixtures is the Asakura-Oosawa-Vrij (AOV) model\textsuperscript{5–7} that describes the polymer chains as spherical particles with a radius equal to the radius of gyration of the polymer. Furthermore, polymer spheres can freely overlap, while they are excluded from a center of mass distance from the colloidal particles. The AOV model has been studied extensively in the past few years, and it was shown that it describes qualitatively the bulk\textsuperscript{8–16} and interfacial phase behavior\textsuperscript{17–22} of mixtures of colloids and polymers. A similar level of agreement was found for the interfacial tension of the gas-liquid\textsuperscript{16,23,24} and wall-fluid interfaces,\textsuperscript{24–26} and for the phase behavior of confined systems.\textsuperscript{27–34}

The quantitative discrepancies between experimental results and the AOV model results can arise from a number of reasons, such as nonideal solvent conditions,\textsuperscript{35} colloid-induced polymer compression,\textsuperscript{36} effect of charges on the colloidal surface,\textsuperscript{37,38} or polymer excluded volume interactions.
In this article, we will concentrate on the latter aspect. The simplest inclusion of polymer interactions was done by introducing a step function interaction between the polymers, i.e., an energy penalty for the overlaps of two polymers. The step potential was used to study the bulk phase diagram and interfacial tension as well as the stability of the floating liquid phase in sedimenting colloid–polymer mixtures with a geometry-based density functional theory (DFT). This approach gives results that are in better agreement with experiments when compared against the AOV model, but the height of the step potential must be introduced as an additional free parameter. Furthermore, we expect the polymer–colloid interaction to be modified as well when considering excluded volume interactions between polymers. Other theoretical approaches have been developed to study the effect of polymer interactions in colloid–polymer mixtures. Aarts et al. extended the free volume theory to include polymer interactions and studied the gas–liquid interfacial tension with the square gradient approximation approach. A one-component perturbative DFT that includes excluded volume interactions and uses the approach of Ref. was developed by Moncho-Jorda et al. to study confined systems and the gas–liquid tension.

Another approach is to describe the polymers as soft spheres, with effective interactions derived from inversion of the center of mass correlation functions in lattice self-avoiding-walk (SAW) polymer simulations. This approach generates soft density-dependent potentials for the polymer–polymer and colloid–polymer interactions, which gives accurate simulation results for the bulk phase behavior that are in quantitative agreement with experimental results. In a similar approach, proposed by Jusufi et al., the effective potentials are derived from off-lattice molecular dynamics simulations of SAW polymer chains. These potentials were used in Monte Carlo simulations to study the bulk phase behavior and the gas–liquid interfacial tension of colloid–polymer mixtures, leading to results in quantitative agreement with experiments.

In this work, we study the effect of excluded volume interactions on the interfacial properties and phase behavior of confined colloid–polymer mixtures with Monte Carlo simulations. We simulate a binary mixture with the density-dependent potentials derived in Ref. and compare the simulation results with those for the AOV model.

II. MODEL

The colloids are treated as hard spheres and the corresponding pair potential reads

\[
\beta v_{cc}(R_{ij}) = \begin{cases} \infty & \text{if } r_{ij} < \sigma_c \\ 0 & \text{otherwise} \end{cases}
\]

where \( R_{ij} = |\mathbf{R}_i - \mathbf{R}_j| \) is the distance between two colloidal particles, with \( \mathbf{R}_i \) the position of the center of mass of colloid \( i \), \( \beta = 1/k_B T \), \( k_B \) is Boltzmann’s constant, and \( T \) the temperature. For the coarse-grained effective polymer–polymer, colloid–polymer, and wall–polymer potentials, we use the expressions of Ref. obtained from microscopic simulations of SAW polymer chains consisting of 500 segments on a lattice and a radius of gyration \( R_g = 16.83 \) lattice units at zero concentration. We introduce the overlap concentration \( \rho^* \) defined by the equation \( \frac{4}{3} \pi \rho^* R_g^3 = 1 \) and the polymer reservoir packing fraction \( \eta_p = \rho_p^* / \rho \), with \( \rho_p^* \) the density in the reservoir of pure polymers in osmotic equilibrium with the two-component system of interest.

The effective density-dependent polymer–polymer interactions read

\[
\beta v_{pp}(r_{ij}, \eta_p) = \sum_{k=1}^{3} a_k(\eta_p) \exp[-r_{ij}(R_g b_k(\eta_p))^2],
\]

where \( R_g \) is the radius of gyration and \( r_{ij} = |\mathbf{r}_i - \mathbf{r}_j| \) is the distance between two polymers, with \( \mathbf{r}_i \) the position of the center of mass of polymer \( i \). The density-dependent parameters are linear in the density, \( a_k = a_k^0 + a_k^1 \eta_p^* \) and \( b_k = b_k^0 + b_k^1 \eta_p^* \). All coefficients, except \( b_k^3 \), are given in Table I. The coefficients \( b_k^3 \) are fixed by imposing the equality of the mean field equation of state,

\[
\beta P(\rho_p) = 1 + \rho_p \beta \tilde{\epsilon}(0) / 2,
\]

for the fitted potentials and the SAW simulations, where the function

\[
\beta \tilde{\epsilon}(0; \rho_p) = 4 \pi \int r^2 \beta v_{pp}(r, \rho_p) dr
\]

is the \( k=0 \) component of the Fourier transform of the polymer–polymer pair potential. In practice, the condition is satisfied by imposing the equality between

\[
\beta \tilde{\epsilon}(0; \eta_p^*) = \pi^{3/2} \sum_{i=1}^{3} a_i(\eta_p^*) b_i(\eta_p^*) \]

derived from Eq. (2) and
The mass of the polymer. The parameters have a quadratic
dependence on the density, given in Table III. In Fig. 2, we show the
interaction between polymers and colloids, and wall-polymer interactions.

\[
\beta v_i^\text{poly}(\mathbf{R}_i - \mathbf{r}_j, \eta_p) = \sum_{k=1}^{2} c_k(\eta_p) \exp[-((\mathbf{R}_i - \mathbf{r}_j)^2 - e_k(\eta_p) + R_g d_k(\eta_p)^2)],
\]

where \(\mathbf{R}_i - \mathbf{r}_j\) is the distance between colloid \(i\) and polymer \(j\). The concentration-dependent parameters are linear in density, given in Table II for size ratio \(q=1.05\).

The interaction between colloidal particles and the hard wall is hard-sphere-like; that is, the colloidal particles cannot penetrate the walls. The interaction between polymers and the hard wall reads

\[
\beta v_{wp}(z, \eta_p) = f_0(\eta_p) \exp[f_1(\eta_p) z/R_g + f_2(\eta_p) z^2/R_g^2 + f_3(\eta_p) z^3/R_g^3],
\]

where \(z\) is the distance between the wall and the center of mass of the polymer. The parameters have a quadratic density dependence \(f_k(\eta_p) = f_{k0} + f_{k1} \eta_p + f_{k2} \eta_p^2\), with \(k=0,1,2,3\). The coefficients are given in Table III. In Fig. 2, we show the effective polymer-polymer, colloid-polymer, and wall-polymer interactions for \(q=1.02995\) as an example.

A final note on the potentials described in this section is in order. Due to a small error in the calculation of the radius of gyration in Ref. 48, all the equations and coefficients presented here were parametrized assuming a radius of gyration \(R_g=16.495\) instead of the correct value of \(R_g=16.83\). The simulations we carried out for this work, as well as the simulations presented in Ref. 51, were done using a size ratio \(q=1.03\) (corresponding to the radius of gyration \(R_g=16.495\)) in the calculations. All the results have been interpreted using the correct value for the size ratio \(q=1.05\) (corresponding to the radius of gyration \(R_g=16.83\)). This correction only changes the values of the polymer packing fraction \(\eta_p\), while the colloid packing fraction \(\eta_c\) is unaffected.

### III. METHOD

We carried out Monte Carlo simulations in the grand canonical ensemble, i.e., with fixed volume, temperature, and chemical potentials \(\mu_c\) and \(\mu_p\) of colloids and polymers, respectively. For each value of \(\mu\), we determined the potentials given in the previous section, at the polymer reservoir packing fraction \(\eta_p(\mu_c)\) calculated by inversion of the equation of state,

\[
\frac{\mu_p}{k_B T} = \log(\rho_p R_g^3) + 0.04658 + 11.05 \rho_p R_g^3 + 35.48 \rho_p R_g^3 - 15.71 R_g^3.
\]

This equation was derived by integrating the Gibbs-Duhem equation with the pressure given by Eqs. (3) and (6).

To study phase coexistence, we sample the probability distribution \(P(N_c)|z_c,\eta_p\) of observing \(N_c\) colloids in a volume \(V\) at fixed colloid fugacity \(z_c\) and fixed polymer reservoir packing fraction \(\eta_p\), using the successive umbrella sampling. 56 We use the histogram reweighting technique to obtain the probability distribution for any \(z_c\) once \(P(N_c)|z_c,\eta_p\) is known for a given \(z_c\),

\[
\ln P(N_c)|z_c,\eta_p = \ln P(N_c)|z_c,\eta_p + N_c \ln \left(\frac{z_c'}{z_c}\right).
\]

At phase coexistence, the distribution function \(P(N_c)\) becomes bimodal with two separate peaks of equal area for the colloidal liquid and gas phases. We determine which \(z_c'\) satisfies the equal area rule,

\[
\int_{0}^{\infty} P(N_c)|z_c',\eta_p dN_c = \int_{-\infty}^{0} P(N_c)|z_c',\eta_p dN_c,
\]

with the average number of colloids.

sampling of the probability ratio is smaller than 5 each window, until the difference between two successive samples were long enough to get good data. Smooth probability distributions in Fig. 3, our simulations reflect on the efficiency of the algorithm. As shown by the acceptance probabilities for the insertion/deletion of polymers were always larger than 40%. The low insertion/deletion probabilities for the insertion/deletion of colloids and polymers. The typical acceptance probabilities for the insertion/deletion of colloids were from 4% to 1% (from low to high colloid density) for state points close to the critical points and from 0.1% to 0.01% at high $\eta_r$. On the other hand, the acceptance probabilities for the insertion/deletion of polymers were always larger than 40%. The low insertion/deletion probabilities of colloidal particles have only an effect on the efficiency of the algorithm. As shown by the smooth probability distributions in Fig. 3, our simulations were long enough to get good data.

The liquid-gas interfacial tension $\gamma_{lg}$ is obtained from $P(N_c)|_{\eta_r,\eta_p}$ at coexistence,$^57$

$$\gamma_{lg} = \frac{1}{2L^2} \left[ \ln \left( \frac{P(N_{c,\max}^g) + P(N_{c,\max}^l)}{2} \right) - \ln(P(N_{c,\min})) \right],$$

where $P(N_{c,\max}^g)$ and $P(N_{c,\max}^l)$ are the maxima of the gas and liquid peaks, respectively, and $P(N_{c,\min})$ is the minimum between the two peaks.

IV. RESULTS

In Sec. II, we explained the straightforward but nontrivial procedure for generating the interaction potentials. It is, therefore, important to check the internal consistency of our calculations. Figure 4 shows the predictions of the equation of state (9) plotted against simulation results of a grand canonical simulation of pure polymers interacting with the potential [Eq. (2)]. In the range of chemical potentials that are relevant for the gas-liquid separation, the simulation results are consistent with the equation of state.

A. Bulk phase behavior and gas-liquid interfacial tension

In Fig. 5, we present the bulk phase diagram obtained from grand canonical Monte Carlo simulations using successive umbrella sampling and histogram reweighting. In particular, Fig. 5(a) shows the phase diagram in the polymer packing fraction $\eta_p$, colloid packing fraction $\eta_c$, representation. These results are consistent with the findings of Ref. 51. The free volume theory$^{58}$ extended to include excluded volume polymer interactions$^{42}$ overestimates the simulation results by almost a factor of 2. This result may be explained by the renormalization group theory expression used in Ref. 42 to evaluate the polymer interactions, which underestimates the correlation length of the polymers. Since the polymers are effectively smaller, a higher number of polymers is needed to drive the demixing transition. Also shown are the experimental results of de Hoog and Lekkerkerker.$^{12}$ The experimental polymer concentration is much larger than those in our simulation results. This discrepancy can be explained by considering the depletion force measurements of Wijting et al.$^{59}$ in the same colloid-polymer system as was used in Ref. 12. They found that the depletion forces are much smaller than expected, probably due to adsorption of the polymers on the colloidal surface. We stress that the potentials used in this work compare well with the experiments of Ramakrishnan et al.$^{60}$ at a size ratio $q=0.67$. $^{51}$

Figure 5(b) shows the phase diagram in the polymer reservoir packing fraction $\eta_{p,r}$, colloid packing fraction $\eta_c$, representation. The discrepancy between our results and those of Ref. 51 is due to a slightly different equation of state used for the conversion of the chemical potential $\mu_p$ to the polymer packing fraction in the reservoir $\eta_{p,r}$. In this work, we inverted Eq. (9), while in Ref. 51, the original SAW equation of state was used. The binodal has a critical point at lower $\eta_{p,r}$, and the density difference between the gas and liquid

\[ \langle N_c \rangle = \int_0^{\infty} N_c P(N_c)|_{\eta_r,\eta_p} dN_c, \]
phases increases for increasing $\eta_c$. This phase diagram is equivalent to the temperature-density phase diagram of a simple fluid, with the polymer reservoir packing fraction playing the role of inverse temperature.

In Fig. 6, we present the simulation results of the dimensionless interfacial tension $\beta \gamma r_c^2$ for the gas-liquid interface, as a function of the difference in packing fractions between the gas and the liquid phase. The interfacial tensions decrease in the case of excluded volume interactions with respect to the AOV model. The comparison between our results and the experiments of Aarts et al. shows that it is difficult to obtain accurate interfacial tension measurements. In addition, we compare our results with the predictions of the extended free volume theory plus a square gradient approximation to evaluate the interpretation of the binodals in the $(\eta_p, \eta_c)$ representation is more straightforward because only $\eta_c$ suffers of the problems described above. We can say that the huge shift in gas densities at coexistence for the confined systems with respect to the bulk binodal is due to the formation of liquid layers at the

FIG. 5. Bulk phase diagram of colloid-polymer mixtures with a size ratio $q=1.05$ for volumes $V=516\sigma_r^3$ (circles) and $2304\sigma_r^3$ (squares). Also shown are the binodals of the AOV model with size ratio $q=1.0$ (dashed lines) and the experimental results of Ref. 51 (solid line). (a) Polymer packing fraction $\eta_p$, colloid packing fraction $\eta_c$, representation. Shown also are the results of the free volume theory with polymer interactions (Ref. 42) (dotted-dashed line) and the experimental results of de Hoog and Lekkerkerker (Ref. 12) (diamonds). (b) Polymer reservoir packing fraction $\eta'_p$, colloid packing fraction $\eta_c$, representation.
walls [see Figs. 8(a) and 8(c)]. The adsorption of colloids at the walls is due to the depletion attraction, which was also observed in the AOV model. However, the thickness of the liquid layer was in that case much smaller than in the present case and the shift in gas density is less pronounced.27,31

Figure 9 displays the phase diagram in the polymer chemical potential $\mu_p$, colloid chemical potential $\mu_c$ representation. These variables do not depend on the definition of the volume and are, therefore, independent of the wall separation distance. This is the ideal representation to compare the binodals for different wall separation distances. The binodals collapse to a single line because of the thermodynamic equilibrium conditions of the gas-liquid coexistence. Regions above the binodal are gaslike, while regions below the binodal are liquidlike. We find a shift of the binodals toward higher polymer chemical potential and smaller colloid chemical potential indicating the occurrence of capillary condensation. Our estimates for the critical points are reported in Table IV.

Also shown in Fig. 9 are the predictions of the Kelvin equation\(^{31}\)

$$\mu_c = \mu_c^{\text{bulk}} + \frac{2}{h}(\gamma_w - \gamma_w^p) \left( \rho_p - \rho_p^c \right) \left( \rho_p - \rho_p^c \right)^2,$$

$$\mu_p = \mu_p^{\text{bulk}} + \frac{2}{h}(\gamma_w - \gamma_w^p) \left( \rho_p - \rho_p^c \right) \left( \rho_p - \rho_p^c \right)^2. \quad (14)$$

The predictions of the Kelvin equation are in good agreement with the simulation results for $H/\sigma_c=16$ and 8 but underestimate the shift for $H/\sigma_c=4$ and 2.

In order to compare the results with those for the AOV model, we scale the binodals by the bulk critical points $(\mu_p^{\text{bulk}}, \mu_c^{\text{bulk}})$, reported in Table IV. Figures 10(a) and 10(b) show that the shift of the binodals and critical points is smaller for the model with interacting polymers than for the AOV model studied in Refs. 27 and 31 for all state points considered. As shown in Fig. 5, the difference $(\rho_p^c - \rho_p^l)$ between the colloid packing fractions of the liquid and the gas at coexistence is smaller for the interacting polymers than for the AOV model for low $\eta_p^c$ but larger for high $\eta_p^c$. On the other hand, Figs. 10(a) and 10(b) show that the shift in chemical potential is always smaller for the interacting polymers than for the AOV model. Therefore, we deduce from Eq. (14) that the difference $\gamma_w - \gamma_w^p$ (liquid-wall and gas-wall interfacial tensions at coexistence) is smaller for the interacting polymer model.

Moncho-Jorda et al.\(^{47}\) have shown that at constant $\eta_p^c$, the excluded volume interactions increase the difference in wall tensions. This is not in contrast with our findings because for capillary condensation, we need to consider the difference in wall tensions at bulk coexistence, that is, at different $\eta_p^c$ for the AOV model and the interacting polymer model.

V. CONCLUSIONS

We have investigated bulk and confined colloid-polymer mixtures, using Monte Carlo simulations. Colloids are treated as hard spheres, while polymers were described as soft repulsive spheres. Colloid-polymer, polymer-polymer, and wall-polymer density-dependent interactions were described by the coarse-grained potentials derived in Ref. 48. We find a bulk phase behavior consistent with the findings of Bolhuis et al.\(^{34}\) Our results for the bulk phase behavior are also similar to those for the AOV model with interacting polymers\(^{42}\) but here, the binodal line lies at higher polymer packing fractions; i.e., the number of polymers needed for the demixing transition is larger. These results are in agreement with the findings of other authors.\(^{44,45,51,55}\) The comparison of our phase diagram with experiments\(^{12}\) is found to be poor for the size ratio $q=1.05$ considered here. This is surprising, since the same interaction potentials provided good agreement with experiments\(^{60}\) at a smaller size ratio.\(^{51}\) In fact, this discrepancy can be explained by considering the results of Wijting et al.\(^{39}\) on depletion potential measurements on the same colloid-polymer mixtures that were used in the phase behavior experiments. These measurements concluded that the depletion attraction was smaller than expected, probably due to polymer adsorption on the surface of the colloids.

On the other hand, better agreement is found for the gas-liquid interfacial tension when compared to the experiments of Aarts et al.\(^{21}\) for the same system. Our results show
that the gas-liquid interfacial tension is smaller for the interacting polymers than for the AOV model. This is in agreement with the works of others on colloid-polymer mixtures with interacting polymers. Both the square gradient approximation and the DFT provide a good description of the simulation results.

In addition, we studied the phase behavior of the mixture confined between two parallel hard walls with separation distances $H/\sigma = 16$, $8$, $4$, and $2$. We find that the hard walls induce capillary condensation and that the theoretical predictions of the Kelvin equation are in reasonable agreement with the simulation results for $H/\sigma = 16$ and $8$ but underestimate the binodal shifts for $H/\sigma = 4$ and $2$. Compared to the AOV model, the excluded volume interactions suppress the capillary condensation. This implies that the effect can only be observed at state points close to bulk coexistence and that smaller plate separations are needed to induce capillary condensation for fixed supersaturation compared with noninteracting polymers. In other words, the Kelvin length is smaller for interacting polymers than for the AOV model. In addition, we observed the formation of rather thick wetting layers at the largest wall separation we studied. This effect seems to be enhanced by the presence of the excluded volume interactions. At large wall separations, the wetting layers provide an effective confinement $H-2t$, with $t$ the thickness of the wetting layer, as was recognized by Derjaguin, which increases effectively the Kelvin length for the colloid-polymer mixtures with excluded volume interactions. The influence of excluded volume interactions on the wetting properties of colloid-polymer mixtures is currently under investigation.

ACKNOWLEDGMENTS

We thank Remco Tuinier for discussions and Arturo Moncho Jordá and Dirk G.A.L. Aarts for their interfacial tension data. This work is part of the research program of the Stichting voor Fundamenteel Onderzoek der Materie (FOM) that is financially supported by the Nederlandse Organisatie voor Wetenschappelijk Onderzoek (NWO). We thank the Dutch National Computer Facilities Foundation for granting access to the LISA supercomputer. NWO-CW is acknowledge for the TOP-CW funding.
