Search for Lepton-Flavor Violation in Z-Boson Decays with \( \tau \) Leptons with the ATLAS Detector

G. Aad et al.\(^*\)

(ATLAS Collaboration)

(Received 1 June 2021; accepted 5 October 2021; published 28 December 2021)

A search for lepton-flavor-violating \( Z \to \ell\ell \) and \( Z \to \mu\tau \) decays with pp collision data recorded by the ATLAS detector at the LHC is presented. This analysis uses 139 \( \text{fb}^{-1} \) of Run 2 pp collisions at \( \sqrt{s} = 13 \text{ TeV} \) and is combined with the results of a similar ATLAS search in the final state in which the \( \tau \) lepton decays hadronically, using the same data set as well as Run 1 data. The addition of leptonically decaying \( \tau \) leptons significantly improves the sensitivity reach for \( Z \to \ell\ell \) decays. The \( Z \to \ell\ell \) branching fractions are constrained in this analysis to \( \mathcal{B}(Z \to \ell\ell) < 7.0 \times 10^{-6} \) and \( \mathcal{B}(Z \to \mu\tau) < 7.2 \times 10^{-6} \) at 95% confidence level. The combination with the previously published analyses sets the strongest constraints to date: \( \mathcal{B}(Z \to \ell\ell) < 5.0 \times 10^{-6} \) and \( \mathcal{B}(Z \to \mu\tau) < 6.5 \times 10^{-6} \) at 95% confidence level.

DOI: 10.1103/PhysRevLett.127.271801

Three lepton families (flavors) exist in the standard model (SM) of particle physics [1–4], and the number of leptons of each family is conserved in their interactions. Nevertheless, this conservation is not postulated by any fundamental principle of the theory, and neutrino oscillations [5,6] indicate that processes violating this conservation do occur in nature. According to current knowledge, lepton-flavor-violating (LFV) processes in charged-lepton interactions can occur via neutrino mixing but are too rare to be detected by current experiments [7]. An observation of these would be an unambiguous sign of physics beyond the SM. LFV processes occur, for example, in models predicting the existence of heavy neutrinos [8], which may also explain the observed tiny masses and large mixing of the SM neutrinos. In such models, up to one in \( 10^9 \) Z bosons would undergo an LFV decay involving \( \tau \) leptons. In an earlier analysis, the ATLAS experiment at the LHC set the strongest constraints on the branching fractions (\( \mathcal{B} \)) of the LFV decays of the Z boson involving a \( \tau \) lepton by searching for such decays in which the \( \tau \) lepton decays hadronically [9]. This result was achieved by analyzing proton-proton (pp) collision data corresponding to an integrated luminosity of 139 \( \text{fb}^{-1} \) at a center-of-mass energy \( \sqrt{s} = 13 \text{ TeV} \) and 20.3 \( \text{fb}^{-1} \) at \( \sqrt{s} = 8 \text{ TeV} \). In that search, ATLAS measured the branching fractions to be \( \mathcal{B}(Z \to \ell\ell) < 8.1 \times 10^{-6} \) and \( \mathcal{B}(Z \to \mu\tau) < 9.5 \times 10^{-6} \) at 95% confidence level (C.L.), superseding former limits set by the LEP experiments of \( \mathcal{B}(Z \to \ell\ell) < 9.8 \times 10^{-6} \) [10] and \( \mathcal{B}(Z \to \mu\tau) < 1.2 \times 10^{-5} \) [11] at 95% C.L.

This Letter presents a complementary search for \( Z \to \ell\ell \) decays (\( \ell = \text{light charged lepton, i.e., } e \text{ or } \mu \)) in which the \( \tau \) leptons decay into electrons or muons (\( \ell\ell \mu \) channel) using 139 \( \text{fb}^{-1} \) of pp collision data at \( \sqrt{s} = 13 \text{ TeV} \) collected by the ATLAS experiment [12–14]. The search is performed here for the first time at the LHC and is combined with the similar ATLAS search using hadronic \( \tau \)-lepton decays (\( \ell\ell\mu \) channel) [9]. The two searches follow similar analysis strategies. Neural network classifiers are used for optimal discrimination of signal from backgrounds and their distributions are employed in a binned maximum-likelihood fit to achieve better sensitivity.

ATLAS is a multipurpose particle detector with a forward-backward symmetric cylindrical geometry and a near 4\( \pi \) coverage in solid angle [12,15,16]. It consists of an inner tracking detector surrounded by a superconducting solenoid, electromagnetic and hadronic calorimeters, and a muon spectrometer based on superconducting air-core toroidal magnets. This search analyzes pp collision events recorded by the ATLAS experiment using single-electron or single-muon triggers [17–19]. Prompt electrons and muons from the Z-boson decays and those from the \( \tau \)-lepton decays are reconstructed and selected in the same way. Candidates for electrons [20], muons [21], jets [22–24], and visible decay products of hadronic \( \tau \)-lepton decays (\( \tau \)\text{had-vis}) [25,26] are reconstructed from energy deposits in the calorimeters and charged-particle tracks measured in the inner detector and the muon spectrometer. These candidates are selected with sets of requirements similar to those used in Ref. [9]. Electron candidates are required to pass the medium likelihood-based identification requirement [20] and have a transverse momentum...
samples of selected events do not overlap with those used a dedicated multivariate algorithm [28]. To ensure the lepton pairs are used for estimates of background required to be smaller than 1.1 in order to reject and have a $p_T > 25$ GeV and pass the tight identification selection. The missing transverse momentum ($E_T^{\text{miss}}$) is calculated as the negative $p_T$ sum of all fully reconstructed and calibrated physics objects [29,30]. Additionally, the calculation includes inner detector tracks that originate from the vertex associated with the hard-scattering process but are not associated with any of the reconstructed objects.

The $Z \rightarrow \ell \ell' \rightarrow \ell \ell' + 2\nu$ signal events are characterized by a final state which has two light charged leptons with different flavor and opposite electric charge, two neutrinos, and an invariant mass of all these particles compatible with the $Z$-boson mass. In most cases, these two leptons are emitted approximately back-to-back in the plane transverse to the proton beam direction. Since the $\tau$ lepton is typically boosted due to the large difference between its mass and the mass of its parent $Z$ boson, the two neutrinos from its decay are usually almost collinear with the charged lepton from the $\tau$-lepton decay. The dominant background contribution is from the lepton-flavor-conserving $Z \rightarrow \tau\tau \rightarrow \ell\ell' + 4\nu$ decays, where the two $\tau$ leptons decay leptonically. Subleading background contributions from other SM processes with final states with two prompt leptons include the decays of a top-antitop-quark pair ($tt$), two gauge bosons (diboson), or a Higgs boson. Finally, small background contributions come from $Z \rightarrow \ell\ell$ decays, where one of the light charged leptons is misidentified with the wrong flavor, and events with “fake leptons.” The latter type of background events includes mostly $W(\rightarrow \ell\nu) +$ jets events with leptons from heavy-flavor quark decays or with light-quark-initiated jets that are misidentified as electrons or muons. The signal and background events are separated by using a set of selection criteria that define a signal-enhanced sample, referred to as the signal region (SR).

The selection criteria are listed in Table I. Three neural network (NN) binary classifiers similar to those used in

<p>| TABLE I. Selection criteria for events in the signal region. The invariant transverse mass of $\ell$ and $E_T^{\text{miss}}$ is defined as $m_T(\ell,E_T^{\text{miss}}) = \sqrt{2p_T(\ell)E_T^{\text{miss}}[1 - \cos(\phi_\ell - \phi_{E_T^{\text{miss}}})]}$. |

Ref. [9] are trained on simulated events to distinguish signal events from $Z \to \tau\tau$, top-quark pair, and diboson background events individually. The input to these NNs is a mixture of low- and high-level kinematic variables, following the same strategy as in the $\ell\tau_{\text{had}}$ channel [9]. The low-level variables are the momentum components of the reconstructed electron and muon candidates, and the $E_T^{\text{miss}}$. The high-level variables are kinematic properties of the $e^+\mu^-E_T^{\text{miss}}$ system, such as the collinear mass $m_{\text{coll}}(e,\mu)$, defined as the invariant mass of the $e^-\mu^-2\nu$ system, where the two neutrinos are assumed to have a vectorial momentum sum that is equal in $p_T$ and the azimuthal angle $\phi$ around the beam axis to the measured $E_T^{\text{miss}}$ and equal in $\eta$ to the subleading $p_T$ lepton momentum. The outputs of the individual NNs (NN$_i$ with values between zero and one) are combined into a final discriminant as shown in Eq. (1), hereafter referred to as the “combined NN output”:

$$\text{combined NN output} = 1 - \sqrt{\frac{1}{3} \sum_{i=1}^{3} (1 - \text{NN}_i)^2}. \quad (1)$$

Events classified by the NN trained for $Z \to \tau\tau$ as backgroundlike are excluded from the SR and used in a control region to better determine the $Z \to \tau\tau$ background in the maximum-likelihood fit (see Table I). The signal acceptance in the SR is 19.5% for the $\mu\tau_{\text{e}}$ channel and 11.2% for the $\mu\tau_{\mu}$ channel, as determined from simulated signal samples. The lower acceptance in the $\mu\tau_{\mu}$ channel is due to the higher $p_T$ threshold on the subleading- $p_T$ lepton and the additional selection on $p_T^{\text{track}}/E_T^{\text{cluster}}$.

Predictions for signal and background contributions are based partly on Monte Carlo (MC) simulations and partly on estimates from data. Signal and background processes were simulated as in Ref. [9]. The signal events were simulated using PYTHIA8 [32] with matrix elements calculated at leading order (LO) in the strong coupling constant. Nominal signal samples were generated with a parity-conserving $Z\tau\tau$ vertex and unpolarized $\tau$ leptons. Scenarios where the decays are maximally parity violating were considered by reweighting the simulated events using TAUSPINNER [33], as discussed in Ref. [9]. The $Z \to \tau\tau$ background events were simulated with the SHERPA2.2.1 [34] generator using the NNPDF 3.0 NNLO PDF set [35] and next-to-leading-order (NLO) matrix elements for up to two partons, and LO matrix elements for up to four partons, calculated with the COMIX [36] and OPENLOOPS [37–39] libraries. Background $Z \to \ell\ell$ events were simulated using the POWHEG-BOX [40] generator with NLO matrix elements. All MC samples include a detailed simulation of the ATLAS detector with GEANT [41,42]. As in Ref. [9], the simulation of $Z$-boson production is improved through a correction derived from measurements in data. The simulated $p_T$ spectra of the $Z$ boson are reweighted to match the unfolded distribution measured by ATLAS in Ref. [43].

The predicted overall yields of signal and $Z \to \tau\tau$ events are determined by a binned maximum-likelihood fit to the combined data in the SR and in a control region enhanced in $Z \to \tau\tau$ events (CRZ$\tau\tau$). This eliminates the theoretical uncertainties in the total $Z$-boson production cross section ($\sigma_Z$), as well as the experimental uncertainties related to the acceptance of the common $\ell\ell'$ final state. The selection criteria for events in the CRZ$\tau\tau$ are the same as those for events in the SR, except that events are required to be classified as $Z \to \tau\tau$-like, i.e., with an output smaller than 0.2 for the $Z \to \tau\tau$ NN and greater than 0.2 for both the top-quark and diboson NNs. In the $\mu\tau_{\mu}$ channel, a small contribution to the total background originates from $Z \to \mu\mu$ events in which one muon is misreconstructed as an electron. Such electron candidates may originate from muons that fail the muon selection requirements and whose tracks are associated with a calorimeter energy cluster and reconstructed as electrons. They may also originate from muons undergoing bremsstrahlung. Such events are modeled with simulation and their predicted yield is based on the measured $\sigma_Z$ [44]. The modeling is validated in a dedicated region which has the same selection as the $\mu\tau_{\mu}$ SR except for the inverse selection on $p_T^{\text{track}}(\ell)/E_T^{\text{cluster}}(\ell)$. Based on the observed level of agreement between data and simulation, a systematic uncertainty of 15% is assigned to the predicted yield of $Z \to \mu\mu$ events in the SR, with no further correction.

Events with fake leptons yield a small but still significant background contribution. In most cases, the fake lepton is the subleading one. These events are estimated from data using a “fake-factor method” similar to the one used in Ref. [9]. The fake factor is defined as the ratio $N_{\text{pass-iso}}^{\text{fake}}/N_{\text{fail-iso}}^{\text{fake}}$, where “fake” indicates events with at least one fake lepton and “pass-iso” or “fail-iso” indicate whether the subleading lepton passes or fails the isolation requirement. The fake factor is measured in events with pairs of same-sign leptons (SS). These events are enhanced in $W(\rightarrow \ell\nu)+\text{jets}$, which is the dominant source of events with fake leptons in the SR. Events in the SS region pass the same event selections as those in the SR except for a same-charge requirement. The fake factors are measured as functions of the transverse momentum and pseudorapidity of the leptons, separately for $e\tau_{\mu}$ and $\mu\tau_{\mu}$ events. The kinematic properties of events with fake leptons in the SR or in the CRs are estimated by the distributions of events with the subleading lepton failing the isolation requirement, but otherwise satisfying all other selection criteria for that region, multiplied by the fake factor. The total predicted yields of the events with fake leptons in the SR and CRs are instead determined by a combined maximum-likelihood fit to data, separately for $e\tau_{\mu}$ and $\mu\tau_{\mu}$ events. The remaining background processes are estimated using simulations. These backgrounds include events from the production and decay of top quarks [32,40], pairs of gauge bosons [34,35], and the Higgs boson [32,40]. The yield of the
events with top quarks is determined in the maximum-likelihood fit to data via the inclusion of a top-quark control region (CRTop). The selection requirements for the CRTop are the same as for the SR except that at least one $b$-tagged jet is required. The expected event yields of the remaining processes are determined based on their production cross section, the integrated luminosity, and the simulated selection efficiency.

A statistical analysis of the selected events is performed to assess the presence of signal events, following the same method used in Ref. [9]. A simultaneous binned maximum-likelihood fit to the combined NN output distribution in the SR, the $m_{\text{coll}}(e, \mu)$ distribution in the CRZ$\tau\tau$, and the event yield in CRTop is used to constrain uncertainties in the predictions and extract evidence of a possible signal. The fit is performed independently for the $e\tau$ and $\mu\tau$ channels. The fraction of $Z \rightarrow e\tau$ events selected in the $\mu\tau$ channel (and vice versa) is negligible and is therefore neglected. In order to improve the discrimination between signal and the events with fake leptons, the events in the SR are further split into two regions based on the transverse momentum of the subleading-$p_T$ lepton $\ell_1$. The low-$p_T$ SR contains events with a $p_T(\ell_1) < 20/25$ GeV in the $e\tau$ (\$\mu\tau\$) channel, while the high-$p_T$ SR contains the events above these thresholds. Both SRs in the $e\tau$ channel have comparable sensitivity, while the low-$p_T$ SR in the $\mu\tau$ channel is more sensitive than the high-$p_T$ SR. Both SRs are fitted simultaneously. There are four unconstrained parameters in the fits: the parameter of interest determines the LFV branching fraction $B(Z \rightarrow \ell\ell')$ by modifying an arbitrary prefit signal yield, $\mu_2$ determines $\sigma_2$ times the overall acceptance and reconstruction efficiency of the $\ell\ell'$ final state in $Z \rightarrow \tau\tau$ and signal events, $\mu_{\text{fake}}$ determines the yield of the top-quark events, and $\mu_{\text{fakes}}$ determines the yield of the events with fake leptons. Constrained parameters are also introduced to account for systematic uncertainties in the signal and background predictions, as in Ref. [9]. These include uncertainties in simulated events in the modeling of trigger, reconstruction, identification and isolation efficiencies, as well as energy calibrations and resolutions of reconstructed objects. No systematic uncertainties are assigned to the overall yields of events with $Z$-boson decays, fake leptons, or top quarks as these yields are determined from data. Uncertainties related to events with fake leptons include statistical uncertainties due to the size of the data sample used to measure the fake factors as well as to model their distributions in the SRs and CRs. Systematic uncertainties assigned to events with fake leptons account for: shape differences in the modeling of the combined NN output in the SS events; differences in the composition of the events with fake leptons between SS events and the events in the SRs; and uncertainties affecting the number of events with prompt leptons failing the isolation requirements as estimated by simulation. The dominant uncertainties of the search are statistical in nature.

Among the systematic uncertainties, the dominant ones are those in the jet calibration which enter through the calculation of the $E_{\text{miss}}^{\text{jet}}$ [24]. A summary of the uncertainties and their impact on the LFV branching fraction is given in Table II.

The observed and best-fit predicted distributions of the combined NN output in the SRs with the highest sensitivity as well as distributions of the collinear mass in the high-$p_T$ SRs are shown in Fig. 1. The best-fit yield of $Z \rightarrow \ell\ell'$ signal corresponds to the branching fractions $B(Z \rightarrow e\tau) = [-2.6 \pm 3.5 \text{(stat)} \pm 2.7 \text{(syst)}] \times 10^{-6}$ and $B(Z \rightarrow \mu\tau) = [-4.4 \pm 3.9 \text{(stat)} \pm 3.4 \text{(syst)}] \times 10^{-6}$. The best-fit yields of $Z \rightarrow \tau\tau$, top quarks, and events with fake leptons are close to the prefit predicted values and are determined with a relative precision of 2%-4%, except the events with fake leptons in the $\mu\tau$ channel, which have an uncertainty of 30%. As no significant excess of data over the predicted background is observed, a combined fit of the $\ell\ell'$ and $\ell\tau_{\text{had}}$ channels is used to set upper limits on $B(Z \rightarrow \ell\ell')$. The analysis of the $\ell\tau_{\text{had}}$ channel with Run 2 data [9] uses a similar scheme of regions and unconstrained parameters. In the statistical combination, the parameters of interest are correlated among the different SRs and CRs. The other unconstrained parameters are uncorrelated as these account either for backgrounds specific to each channel or for different acceptances of the $\ell\ell'$ or $\ell\tau_{\text{had}}$ final states. Common systematic uncertainties are correlated, besides those related to the jet energy calibrations, which are uncorrelated.
This conservative correlation scheme was chosen because of different best-fit values for the parameters associated with these uncertainties in the two channels. However, the fit with correlated jet energy calibration uncertainties yields compatible combined upper limits. The analysis of the \( \ell \tau_{\text{had}} \) channel with Run 1 data is combined using the same correlation scheme as in Ref. [9]. The combined best-fit amount of \( Z \rightarrow \ell \tau \) signal corresponds to the branching fractions \( B(Z \rightarrow \ell \tau) = [-1.4 \pm 2.5 \text{(stat)} \pm 1.8 \text{(syst)}] \times 10^{-6} \) and \( B(Z \rightarrow \mu \tau) = [1.7 \pm 2.2 \text{(stat)} \pm 1.6 \text{(syst)}] \times 10^{-6} \).

Since no significant deviation from the SM background hypothesis is observed, exclusion limits are set using the CL\(_S\) method [45]. The upper limits are shown in Table III for LFV...
decays with different assumptions about the $\tau$-polarization state. The polarization of the $\tau$ lepton affects the energy of its visible decay products and thus the acceptance for signal events. In the scenario where the $\tau$ leptons are unpolarized, the observed upper limits at 95% C.L. on $B(Z \to \ell\tau)$ and $B(Z \to \mu\tau)$ are $5.0 \times 10^{-6}$ and $6.5 \times 10^{-6}$, respectively.

In conclusion, this Letter reports the first analysis of the $Z \to \tau\tau$ channel in the search for LFV Z-boson decays at the LHC. This channel yields a sensitivity similar to the $Z \to \ell\ell$ channel. With the combined results of the two channels, the ATLAS experiment sets the most stringent constraints on LFV Z-boson decays involving $\tau$ leptons to date. The precision of these results is mainly limited by statistical uncertainties.

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently. We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWFW and FWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; ANID, Chile; CAS, MOST and NSFC, China; Minciencias, Colombia; MSMT CR, MPO CR and VSC CR, Czech Republic; DNRF and Danish Natural Science Research Council, Denmark; IN2P3-CNRS and CEA-DRF/IRFU, France; Shota Rustaveli National Science Foundation of Georgia, Georgia; BMBF, HGF and MPG, Germany; General Secretariat for Research and Innovation, Greece; RGC and Hong Kong SAR, China; ISF and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; NWO, Netherlands; Research Council of Norway, Norway; MNiSW and NCN, Poland; FCT, Portugal; MNE/IFA, Romania; JINR; Ministry of Education and Science of the Russian Federation and NRC KI, Russian Federation; Ministry of Education, Science and Technological Development, Serbia; Ministry of Education, Science, Research and Sport, Slovakia; ARRS and Ministry of Education, Science and Sport, Slovenia; DSI/NRF, South Africa; MICINN, Spain; Swedish Research Council and Wallenberg Foundation, Sweden; Secretariat for Education and Research, Switzerland, SNSF and Cantons of Bern and Geneva, Switzerland; MOST, Taiwan; TAEK, Turkey; STFC, United Kingdom; DOE and NSF, USA In addition, individual groups and members have received support from BCKDF, CANARIE, Compute Canada and CRC, Canada; COST, ERC, ERDF, Horizon 2020 and Marie Skłodowska-Curie Actions, European Union; Investissements d’Avenir Labex, Investissements d’Avenir Idex and ANR, France; DFG and AvH Foundation, Germany; Herakleitos, Thales and Aristeia programmes co-financed by EU-ESF and the Herakleitos, Thales and Aristeia programmes co-financed by EU-ESF and the Greek NSRF, Greece; BSF-NSF and GIF, Israel; Norwegian Financial Mechanism 2014-2021, Norway; La Caixa Banking Foundation, CERCA Programme Generalitat de Catalunya and PROMETEO and GenT Programmes Generalitat Valenciana, Spain; Göran Gustafssons Stiftelse, Sweden; The Royal Society and Leverhulme Trust, United Kingdom. The crucial computing support from all WLCG partners is acknowledged gratefully, in particular from CERN, the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INFN-CNAF (Italy), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (UK) and BNL (USA), the Tier-2 facilities worldwide and large non-WLCG resource providers. Major contributors of computing resources are listed in Ref. [46].

TRIUMF, Vancouver BC, Canada

Department of Physics and Astronomy, York University, Toronto ON, Canada

Division of Physics and Tomonaga Center for the History of the Universe, Faculty of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan

Department of Physics and Astronomy, Tufts University, Medford, Massachusetts, USA

Department of Physics and Astronomy, University of California Irvine, Irvine, California, USA

Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden

Department of Physics, University of Illinois, Urbana, Illinois, USA

Instituto de Física Corpuscular (IFIC), Centro Mixto Universidad de Valencia—CSIC, Valencia, Spain

Department of Physics, University of British Columbia, Vancouver BC, Canada

Department of Physics and Astronomy, University of Victoria, Victoria BC, Canada

Fakultät für Physik und Astronomie, Julius-Maximilians-Universität Würzburg, Würzburg, Germany

Department of Physics, University of Warwick, Coventry, United Kingdom

Waseda University, Tokyo, Japan

Department of Particle Physics and Astrophysics, Weizmann Institute of Science, Rehovot, Israel

Department of Physics, University of Wisconsin, Madison, Wisconsin, USA

Fakultät für Mathematik und Naturwissenschaften, Fachgruppe Physik, Bergische Universität Wuppertal, Wuppertal, Germany

Department of Physics, Yale University, New Haven, Connecticut, USA

Deceased.

Also at Department of Physics, King’s College London, London, United Kingdom.

Also at Istanbul University, Dept. of Physics, Istanbul, Turkey.

Also at Instituto de Fisica Teorica, IFT-UAM/CSIC, Madrid, Spain.

Also at TRIUMF, Vancouver BC, Canada.

Also at Department of Physics, University of Fribourg, Fribourg, Switzerland.

Also at Department of Physics and Astronomy, University of Louisville, Louisville, Kentucky, USA.

Also at Departament de Fisica de la Universitat Autonoma de Barcelona, Barcelona, Spain.

Also at Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia.

Also at Faculty of Physics, Sofia University, 'St. Kliment Ohridski’, Sofia, Bulgaria.

Also at Department of Physics, Ben Gurion University of the Negev, Beer Sheva, Israel.

Also at Universita di Napoli Parthenope, Napoli, Italy.

Also at Instituto de Partículas y del Cosmos, IFIC, Valencia, Spain.

Also at Bruno Kessler Foundation, Trento, Italy.

Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg, Russia.

Also at Borough of Manhattan Community College, City University of New York, New York, New York, USA.

Also at Department of Physics, California State University, Fresno, USA.

Also at Department of Financial and Management Engineering, University of the Aegean, Chios, Greece.

Also at Centro Studi e Ricerche Enrico Fermi, Rome, Italy.

Also at Department of Physics, California State University, East Bay, USA.

Also at Institucio Catalana de Recerca i Estudis Avancats, ICREA, Barcelona, Spain.

Also at Graduate School of Science, Osaka University, Osaka, Japan.

Also at Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Freiburg, Germany.

Also at University of Chinese Academy of Sciences (UCAS), Beijing, China.

Also at Institute of Particle and Nuclear Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan.

Also at Yeditepe University, Physics Department, Istanbul, Turkey.

Also at CERN, Geneva, Switzerland.

Also at Joint Institute for Nuclear Research, Dubna, Russia.

Also at Hellenic Open University, Patras, Greece.

Also at Center for High Energy Physics, Peking University, China.

Also at The City College of New York, New York, New York, USA.

Also at Department of Physics, California State University, Sacramento, USA.

Also at Département de Physique Nucléaire et Corpusculaire, Université de Genève, Genève, Switzerland.

Also at Faculty of Physics, M.V. Lomonosov Moscow State University, Moscow, Russia.

Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany.

Also at CPPM, Aix-Marseille Université, CNRS/IN2P3, Marseille, France.

Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary.

Also at Giresun University, Faculty of Engineering, Giresun, Turkey.

Also at Department of Physics and Astronomy, Michigan State University, East Lansing, Michigan, USA.

Also at Institute of Theoretical Physics, Ilia State University, Tbilisi, Georgia.
