**Abstract**

**Background:** The eradication of facultative intracellular bacterial pathogens, like *Salmonella typhi*, requires the concerted action of both the humoral immune response and the cytotoxic CD8⁺ T cell response. Dendritic cells (DCs) are considered to orchestrate the cytotoxic CD8⁺ T cell response via cross-presentation of bacterial antigens onto MHC class I molecules. Cross-presentation of *Salmonella* by DCs however, is accompanied by the induction of apoptosis in the DCs. Besides antibody production, B cells are required to clear *Salmonella* infection for other unknown reasons.

**Methodology/Principal Findings:** Here we show that *Salmonella*-specific B cells that phagocytose *Salmonella* upon BCR-ligation reanimate human memory CD8⁺ T cells via cross-presentation yielding a *Salmonella*-specific cytotoxic T cell response. The reactivation of CD8⁺ T cells is dependent on CD4⁺ T cell help. Unlike the DCs, B cell-mediated cross-presentation of *Salmonella* does not coincide with apoptosis.

**Conclusions/Significance:** B cells form a new player in the activation of the cytotoxic effector arm of the immune response and the generation of effective adaptive immunity in *Salmonella* infection.

**Introduction**

*Salmonella* is a pathogenic bacterium that causes severe disease in mice and man. *Salmonella typhi* (*Salmonella enterica serovar Typhi*) causes invasive diseases in human, which has many features in common with *Salmonella typhimurium* in mice. The gastrointestinal tract is the major site of primary infection of the host and has to be passed before systemic infection can occur. One way to infect the host cells is via sampling of bacteria by DCs in the intestine. In *in vitro* studies showed that DCs located in the lamina propria under the gut epithelium of the small bowel extend processes across the tight junctions between the epithelial cells and capture bacteria from the luminal side of the gut [1,2]. The major route of infection however, is via microfold cells or M cells [3,4]. The specialized antigen-sampling M cells are located in the dome region of the Peyer’s Patches and encounters an extensive network of resident macrophages, DCs and great numbers of B cells [15,16]. Instead of being immediately destroyed by these cells, *Salmonella* have evolved several mechanisms to survive in the harsh milieu of phagosomal compartments [17] and can be cytotoxic to macrophages by inducing apoptosis *in vitro* [18,19].

After transcytosis by M cells, *Salmonella* reaches the subepithelial dome of the Peyer’s patches and encounters an extensive network of resident macrophages, DCs and great numbers of B cells [15,16]. Instead of being immediately destroyed by these cells, *Salmonella* have evolved several mechanisms to survive in the harsh milieu of phagosomal compartments [17] and can be cytotoxic to macrophages by inducing apoptosis *in vitro* [18,19].

Recently, we showed that recognition of *Salmonella* via the specific B cell receptor (BCR) on B cells results in internalization of *Salmonella*. *Salmonella* is able to survive intracellularly in primary B cells in a non-replicative state [20]. Following uptake of *Salmonella*, B cells do not go into apoptosis, but differentiate and start to produce *Salmonella*-specific antibodies. In addition, BCR-mediated phagocytosis of *Salmonella* by B cells leads to antigen presentation via MHC class II and subsequent CD4⁺ T cell activation, which in turn boosts antibody production by the infected B cell.
Antibody transfer studies have shown that the requirement for B cells in the clearance of Salmonella does not solely depend on antibody formation [21]. Which additional immune responses need B cell involvement remains unclear. For clearance of Salmonella, not only the humoral immune response is required, but also the activation of cytotoxic CD8+ T cells is needed to eliminate Salmonella-infected cells. Recently, DCs have been shown to activate Salmonella-specific CD8+ memory T cells after direct uptake of bacteria or via suicide cross-presentation after uptake of S. typhi-infected human cells [22]. As the generation of Salmonella antigens for MHC class II molecules is an efficient process in infected B cells, we tested whether BCR-mediated phagocytosis also leads to cross-presentation of Salmonella antigens via the MHC class I pathway of B cells and whether this elicits a cytotoxic T cell response against Salmonella-infected cells.

Here we show that Salmonella-specific primary B cells that have internalized Salmonella do cross-present Salmonella antigens via MHC class I in a proteasome-dependent manner. Cross-presentation of Salmonella antigens by B cells reactivates Salmonella-specific CD8+ memory cells that acquire a cytotoxic phenotype and are efficient in killing of Salmonella-infected cells. Thus, antigen-specific B cells are an under appreciated type of cell for the induction of a cytotoxic T cell response against facultative intracellular bacteria.

Results

Salmonella-infected B Cells Initiate a CD8+ T Cell Response

To study MHC class I antigen presentation by B cells, we used Salmonella typhimurium as a model for cross-presentation against facultative intracellular bacteria. Previously, we showed that about 4% of the B cells recognize Salmonella by their BCR, phagocytose Salmonella, and subsequently initiate a CD4+ T cell response [20]. Now, we investigated whether Salmonella-infected B cells are also capable to induce a cytotoxic CD8+ T cell response. B cells were incubated with Salmonella to allow phagocytosis of the bacteria by B cells. After extensive washing, the Salmonella-infected B cells were cocultured with CFSE-labeled CD4+ and CD8+ T cells. As observed before, B cells that had phagocytosed Salmonella induced CD4+ T cell proliferation [20]. Interestingly, a considerable amount of CD8+ T cells had proliferated as well (Fig. 1A and B). Since the amount of B cells that specifically recognize Salmonella via the BCR is quite low, we maximized the T cell responses by enhancing the uptake of Salmonella by B cells using Salmonella coated with a tetrameric antibody complex, consisting of anti-LPS antibodies and anti-IgM-BCR antibodies. As a result, all B cells expressing an IgM-BCR, recognize Salmonella and phagocytose the bacterium via their BCR. This resulted in an uptake of Salmonella by about 30% to 60% of the B cells (data not shown) and a strong increase in CD8+ T cell proliferation in B/T co-culture experiments. Next, we investigated the requirement of CD4+ T cell help for the proliferation of the CD8+ T cells. Salmonella-infected B cells were cultured with CD8+ T cells in the absence of CD4+ T cells. This situation almost completely abolished proliferation of the CD8+ T cells with both naturally phagocytosed Salmonella-infected B cells or coated Salmonella-infected B cells (Fig. 1C and D). Thus, B cells infected by Salmonella act as antigen presenting cells and induce CD8+ T cell proliferation, but activation of CD8+ T cells requires the simultaneous CD4+ T cell activation to enable T cell help. To study which kind of help CD4+ T cells provide for CD8+ T cell proliferation, we looked at the requirement of IL-2, by adding blocking antibodies to the culture of infected B cells and CD4+ and CD8+ T cells. This resulted in a very strong reduction of CD8+ T cell proliferation (Fig. S1). However, CD4+ T cell proliferation was also decreased (data not shown). Therefore we performed a converse experiment, by adding IL-2 instead of CD4+ cells to the co-culture of infected B cells and CD8+ T cells. This shows that substitution of CD4+ T cell help by IL-2 also induces CD8+ T cell proliferation by B cells that have phagocytosed Salmonella (Fig. 1E). The addition of IL-2 to the co-culture with non-infected B cells did not induce significant proliferation of CD8+ T cells, indicating that IL-2 itself does not stimulate non-specific CD8+ T cell proliferation. Furthermore, the role of CD40 stimulation was studied. Since CD40-CD40L interactions do also play a role in CD4+ T cell activation, CD4+ T cell help was substituted by IL-2. Blocking CD40 resulted in reduction of CD8+ T cell proliferation (Fig. 2E). Thus CD8+ T cells help is partially mediated by both IL-2 and CD40-CD40L interactions.

Although CD8+ T cells proliferate only in presence Salmonella-infected B cells and CD4+ T cell help, we cannot exclude that the CD8+ T cell response is partly an effect of bystander proliferation, for instance via soluble factors. Therefore, we studied the T cell response in more detail. Culture supernatant of infected B cells in presence of CD4+ T cell help was not able to induce CD8+ T cell proliferation (data not shown). In addition, blocking experiments, in which CD8+ T cell activation was prevented via anti-CD8 blocking antibodies, resulted in a decrease of CD8+ T cell activation by Salmonella-infected B cells (Fig. S1). To study Salmonella-specific T cell proliferation in more detail, restimulation of the T cells was studied. Proliferating CD8+ T cells which respond to Salmonella-infected B cells were sorted. These Salmonella-responsive T cells were restimulated with autologous B cells which were infected with Salmonella, or anti-IgM coated Salmonella to maximize the infection rate. During restimulation additional IL-2 was added for help, and CD8+ T cell proliferation was measured using CFSE labeling. This showed that CD8+ T cells are primary Salmonella-specific, because they proliferate mainly upon restimulation with Salmonella-infected B cells (Fig. 1F). In addition, we analyzed clonality of the Salmonella-specific T cell response using a TCR beta clonality assay, as an additional indication for antigen-specific T cell activation. Proliferating CD8+ T cells, which were activated by Salmonella-infected B cells, and non-proliferating CD8+ T cells, which did not respond, were both sorted and tested for clonal TCR beta gene rearrangements. Subsequently, CD8+ T cells were stimulated with anti-CD3 and anti-CD28 antibodies to obtain non-specific proliferated T cells. The CD8+ T cells which proliferate upon Salmonella-infected B cells show a clear clonality (Fig. 1G). In contrast, neither CD8+ T cells did proliferate after culturing with infected B cells, nor non-specific CD8+ T cells proliferating cells show a clear TCR clonality. Thus, primary B cells which have phagocytosed Salmonella elicit CD8+ T cell proliferation, which is mainly Salmonella-specific.

Salmonella-infected B Cells Activate Both the Central Memory and Effector Memory CD8+ Compartment

Do B cells elicit a naive or a memory CD8+ cell response? To study this, we cultured the total CD8+ T cell population with or without Salmonella-infected B cells, in presence of CD4+ T cells for help, and determined the naive (CD45RO−CD27−; T N), central memory (CD45RO−CD27+; T CM), effector memory (CD45RO+CD27−; T EM) or terminal effector (CD45RO−CD27−; T E) phenotype of the CD8+ T cells after prolonged culture. Upon 11 days of culture, purified CD8+ T cells show mainly a naive phenotype. In contrast, following activation with Salmonella-infected B cells, the CD8+ T cell population shifts towards the T EM phenotype (Fig. 2A). CD8+ T cells that are activated with Salmonella-infected B cells in the absence of CD4+ T help, do not differentiate to a T EM phenotype (Fig. 2B).
Next, we investigated if Salmonella-infected B cells can prime naïve T cells at all. Therefore we studied proliferation of sorted naïve (CD45RA⁺CD45RO⁻; T_{N}) or memory (CD45RA⁻CD45RO⁺; T_{M}) CD8⁺ T cells in response to Salmonella-infected B cells.

Figure 2C illustrates that the naïve CD8⁺ population do not proliferate over background values upon stimulation with Salmonella-infected B cells, whereas the memory CD8⁺ T cells proliferated vigorously. Further discrimination of the memory subset by sorting...
Figure 2. *Salmonella*-infected B cells reactivate a CD8$^+$ memory response. (A) CD4$^+$ and CD8$^+$ T cells were cultured alone (T), together with B cells (B + T) or with anti-IgM-coated *Salmonella*-infected B cells (B$_{Sal}$ + T). After 11 days, cells were stained for CD45RO and CD27 to discriminate between the different T cell populations: naïve (T$_N$; CD45RA$^+$CD27$^+$), central memory (T$_{CM}$; CD45RO$^+$CD27$^+$), effector memory (T$_{EM}$; CD45RO$^-$CD27$^+$) and terminal effector (T$_E$; CD45RA$^-$CD27$^-$) T cells. Gated CD8$^+$ cells were analyzed. (B) Without CD4$^+$ T cells, the differentiation of CD8$^+$ T cells to effector memory is attenuated. Data are mean ± SEM from five independent experiments. (C) Coated *Salmonella*-infected B cells activate proliferation of sorted CD8$^+$CD45RO$^+$ cells (T$_{MEM}$), but not of purified CD8$^+$CD45RA$^+$ cells (T$_N$) in the presence of CD4$^+$ help. Data are mean ± SEM from three independent experiments. (D) Coated *Salmonella*-infected B cells activate proliferation of sorted CD8$^+$CD45RO$^+$CD27$^+$ (T$_{CM}$) and CD8$^+$CD45RO$^-$CD27$^-$ (T$_{EM}$) cells. Data are mean ± SEM from four independent experiments. (E) Sorted naïve or memory CD8$^+$ T cells were cocultured with B cells or DCs, naturally infected with *Salmonella* (Sal$^*$), in presence of CD4$^+$ T cell help. Proliferation of the naive or memory CD8$^+$ T cells was measured at day 6. Data shown are from one representative experiment of two independent experiments with different donors. (F) Sorted naïve or memory CD8$^+$ T cells were cocultured with B cells or DCs, infected with coated *Salmonella* (Sal), in presence of CD4$^+$ T cell help. Proliferation of the naive or memory CD8$^+$ T cells was measured at day 6. Data shown are from one representative experiment of two independent experiments with different donors.

doi:10.1371/journal.pone.0013016.g002
T_{CM} (CD45RO^+CD27^+) and T_{EM} (CD45RO^+CD27^-) CD8^+ T cells, followed by co-culture with Salmonella-infected B cells, showed that both T_{CM} and T_{EM} can be activated by Salmonella-infected B cells, although that T_{EM} proliferate less compared to T_{CM} (Fig. 2D). Recent experiments in mice show that both T_{CM} and T_{EM} cells can arise from activation and proliferation of the T_{CM} compartment, whereas T_{EM} cells are more terminally differentiated and therefore proliferate poorly and only give rise to T_{EM} progeny [23]. Indeed, expansion of the sorted T_{EM} by Salmonella-infected B cells yielded offspring with both a T_{CM} and a T_{EM} phenotype, whereas T_{EM} activation yielded mainly T_{EM} progeny (data not shown). In addition, the effectiveness of T cell activation by infected B cells was compared using another antigen presenting cell, a dendritic cell (DC). After uptake of Salmonella, the DCs matured (data not shown) and were capable to activate both naive (T_N) and memory CD8^+ T cells (T_{MEM}), whereas B cells could only reactivate memory CD8^+ T cells (Fig. 2E). However, the percentage of B cells that had taken up Salmonella was much lower compared to the DCs that had taken up Salmonella (Fig. S2). To correct for these differences in uptake, we also used anti-IgM coated Salmonella, to enhance the number of Salmonella-infected B cells. Indeed this yielded comparable amounts of Salmonella-infected B cells and DCs (Fig. S2). In this setting, Salmonella-infected B cells were even superior in activation of memory CD8^+ cells (Fig. 2F). So, upon Salmonella-infection, B cells can reactive CD8^+ memory cells in the same manner as DCs. In summary, these data show that Salmonella-infected B cells activate an effective recall response of memory CD8^+ T cells, yielding expansion of both the “memory stem cell” containing T_{CM} compartment and the memory effector cell containing T_{EM} compartments.

**Activated Salmonella-specific CTLs are Able to Kill Salmonella-infected Cells**

Activation of cytotoxic CD8^+ T cells by B cells is controversial. Earlier reports showed that B cells induce tolerance or anergy in CD8^+ T cells. In contrast, we showed proliferation of CD8^+ T cells upon activation by antigen-specific B cell upon phagocytosis of Salmonella. Although this proliferation is unlikely to yield tolerance, proliferation itself does not guarantee that the activated CD8^+ T cells have acquired a functional anti-bacterial phenotype. CD8^+ T cells kill intracellular pathogens either via secretion of IFN-γ or via direct killing of the infected target cell [24]. To investigate if Salmonella-containing B cells induce a functional CD8^+ T cell response, IFN-γ secretion of the activated CD8^+ T cells was measured. This showed that, after culture with Salmonella-infected B cells, the number of CD8^+ T cells producing IFN-γ is increased to more than 65% (Fig. 3A and 3B). Thus, cross-presentation of Salmonella antigens by B cells induces not only proliferation of the CD8^+ T cells but also renders the cells functional in that it induces IFN-γ secretion.

As these data demonstrate that B cells that had taken up Salmonella are able to functionally activate CD8^+ T cells, the question remained if the activated CD8^+ T cells were Salmonella-

---

**Figure 3.** Salmonella-infected B cells induce Salmonella-specific CD8^+ T cells to secrete IFN-γ and are cytotoxic. (A) CD4^+ and CD8^+ T cells were cultured alone (T), with B cells (B + T) or with anti-IgM-coated Salmonella-infected B cells (B_{Sal} + T). After 11 days, CD8^+ T cells were stimulated for 5 hours with PMA, ionomycin and BFA and analyzed for IFN-γ production by intracellular FACS staining. A representative experiment of five independent experiments using cells from different healthy donors is shown. (B) Salmonella-infected B cells induce IFN-γ expression by CD8^+ T cells compared to non-infected B cells. Data are means ± SEM from five independent experiments of different donors and ** p < 0.01. (C) CD8^+ T cells were primed with coated Salmonella-infected B cells and the proliferating CD8^+ T cells were sorted after 6 days, expanded with IL-2 for another 6 days and restimulated with autologous B cells that had either or not phagocytosed Salmonella. Salmonella-specific degranulation was measured by CD107a expression at the plasma membrane CD8^+ T cells. Data are means ± SEM of five independent experiments of different donors, and ** p < 0.01. (D) Proliferating CD8^+ T cells primed with B cells that had naturally phagocytosed Salmonella were sorted and CD107a expression was measured upon re-encounter of B cells (T + B), B cells naturally infected with Salmonella (T + B_{Sal}) or anti-IgM-coated Salmonella (T + B_{Sal}Ig). Data are of two experiments. (E) Sorted Salmonella-primed CD8^+ T cells (see C) specifically kill Salmonella-infected B cells as measured by ^51Cr release of autologous B cells that were either or not infected with Salmonella. Data are expressed as mean ± SEM, of six independent experiments of different donors, and ** p < 0.01. (F) Sorted Salmonella-primed CD8^+ T cells (see C) do not kill Staphylococci-infected B cells as measured by ^51Cr release of autologous B cells that were either infected with Salmonella or with Staphylococci. The data are expressed as mean ± SEM, of two independent experiments of different donors.

doi:10.1371/journal.pone.0013016.g003
specific and whether CD8\(^{+}\) T cells can acquire a cytotoxic phenotype through B cell-mediated activation. First, we investigated if the CD8\(^{+}\) T cells degranulate their toxic granules upon recognition of Salmonella-infected target cells. For this we analyzed expression of the marker CD107a, which is expressed at the plasma membrane of CD8\(^{+}\) T cells upon degranulation. Salmonella-infected B cells were cultured together with CFSE labeled CD4\(^{+}\) and CD8\(^{+}\) T cells. The proliferating Salmonella-primed CD8\(^{+}\) T cells were sorted after 6 days, expanded and re-exposed to autologous B cells that had been infected to high percentages with anti-IgM-coated Salmonella after which CD107a expression was measured. Upon re-exposure to Salmonella-infected B cells, the Salmonella-primed CD8\(^{+}\) T cells show a strong and significant increase of CD107a expression at the plasma membrane. Since the proliferating CD8\(^{+}\) T cells did not show degranulation when re-exposed to autologous, non-infected B cells, Salmonella-primed CD8\(^{+}\) T cells degranulate specifically upon recognition of Salmonella-infected cells (Fig. 3C). To exclude the possibility that the anti-IgM coating of Salmonella had affected our results, we also primed CD8\(^{+}\) T cells with Salmonella-specific B cells that had naturally phagocytosed Salmonella via their antigen-specific BCR. These primed CD8\(^{+}\) T cells degranulated specifically upon recognition of autologous B cells naturally infected with Salmonella, of which a relative small percentage (5–10\%, data not shown) contained Salmonella-infected antigen-specific B cells (Fig. 3D; middle bar). In addition, the naturally Salmonella-primed CD8\(^{+}\) T cells very efficiently degranulated upon contact with autologous B cells of which a higher percentage (26–46\%, data not shown) of cells had been infected with anti-IgM coated Salmonella (Fig. 3D, right bar). Finally, we investigated if degranulation of the Salmonella-specific CD8\(^{+}\) T cells also leads to death of the Salmonella-infected cells to determine the true cytotoxic efficacy of the lytic granules. CFSE labeled CD8\(^{+}\) T cells were primed by incubation with Salmonella-infected B cells. Proliferating CD8\(^{+}\)/CFSE\(^{\text{low}}\) cells were sorted and expanded for another 6 days. Re-exposure of the Salmonella-primed T cells to Salmonella-infected, \(^{31} \text{Cr}\)-labeled autologous B cells demonstrated that the primed CD8\(^{+}\) T cells killed Salmonella-infected B cells but not non-infected B cells (Fig. 3E). In addition, the Salmonella-primed CD8\(^{+}\) T cells were not able to kill B cells that had phagocytosed Staphylococci via BCR ligation (Fig. 3F), demonstrating that the CD8\(^{+}\) T cells are indeed at least partly Salmonella-specific and do not recognize autologous B cells that are activated via BCR-mediated uptake of other bacteria. Thus, activation of CD8\(^{+}\) T cells by B cells cross-presenting Salmonella antigens induces a cytotoxic phenotype in the CD8\(^{+}\) T cells that specifically mediates killing of Salmonella-infected cells.

### Cross-Presentation of Salmonella-antigens is Partly Proteasome Dependent

We showed that after phagocytosis of Salmonella, B cells are able to cross-present antigens to CD8\(^{+}\) T cells and thereby initiate a Salmonella-specific cytotoxic T cell response. The mechanism of cross-presentation of Salmonella antigens by B cells is unknown. One likely mechanism is that after phagocytosis, antigens are translocated from the Salmonella-containing vacuole (SCV) into the cytoplasm of B cells. Next, the antigens are degraded in the cytoplasm by proteasomes into small peptides, which are presented via the classical MHC class I antigen presentation route. To investigate this mechanism of cross-presentation, we used a chemical compound that specifically blocks the proteasome (MG-132). To study the effect of cross-presentation when blocking the proteasome, we used the CD107a degranulation assay. Re-exposure of Salmonella-primed CD8\(^{+}\) T cell to autologous, Salmonella-infected B cells showed that Salmonella-infected B cells are much less efficient in inducing CD8\(^{+}\) T cell degranulation when proteasomes are inhibited (Fig. 4). In addition, proteasome inhibition of the infected B cells also prevents killing by Salmonella-specific CD8\(^{+}\) T cells (data not shown). This observation implies that the proteasome is somehow involved in cross-presentation of Salmonella antigens by B cells. How the proteasome is involved is unclear as proteasome inhibition has many secondary effects on the ubiquitin cycle, the modification of histones and the formation of multivesicular bodies [25].

### B Cells do not Cross-Present Heat-killed Salmonella

Salmonella survives inside a cell via expression of the TTSS that create an intracellular environment that neutralizes the destructive forces of the host cell [26]. The TTSS components SPI-1 and SPI-2 play a role in this process by exporting proteins into the host cell. Because of the capacity of Salmonella to invade cells and to control its maintenance inside the cell via SPI-1 and SPI-2, it is possible that Salmonella itself might play a direct role in the cross-presentation pathway in B cells. To determine the role of SPI-1 and SPI-2 in cross-presentation of Salmonella by B cells, we analyzed CD8\(^{+}\) T cells proliferation via co-culture with CD4\(^{+}\) T cells and B cells that had phagocytosed anti-IgM-coated wild type Salmonella, or Salmonella with a mutation in SPI-1 (invA\(^{-}\)) or SPI-2 (ssrA\(^{-}\)). Both Salmonella mutants were still able to elicit a CD8\(^{+}\) T cell response, albeit at lower percentages of T cell proliferation compared to wild type Salmonella (Fig. 5A). Thus SPI-1 and SPI-2 each contribute to cross-presentation of Salmonella antigens by B cells, but are not essential.

By creating an environment in which Salmonella itself cannot be killed, it is possible that the intracellular survival plays a role in the efficacy of cross-presentation of Salmonella antigens by B cells. To
study the contribution of Salmonella on the efficacy of cross-presentation of Salmonella antigens, we compared the efficiency of living and dead Salmonella to induce CTL activation. CD8\(^{+}\) T cells were primed with B cells infected with living or heat-killed Salmonella. After sorting and expansion, the Salmonella-primed T cells were re-exposed to autologous B cells that had either or not phagocytosed living or dead Salmonella. Cross-presentation of Salmonella antigen was measured by the extent of degranulation of the primed T cells using CD107a expression. CD8\(^{+}\) T cells that had been primed by B cells infected with living Salmonella efficiently degranulated upon recognition of autologous B cells that had phagocytosed living Salmonella (upregulation of CD107a to 60%), whereas the cells did not degranulate upon contact with B cells that had phagocytosed dead Salmonella (Fig. 5B; left panel). This indicates either that B cells present different Salmonella antigens to CD8\(^{+}\) T cells from live or dead bacteria or that B cells cannot cross-present Salmonella antigens when the intracellular bacterium is not alive. Furthermore, CD8\(^{+}\) T cells that had been primed with B cells that had taken up dead Salmonella showed poor degranulation to B cells that had taken up either live or heat-killed Salmonella (Fig. 5B; right panel), demonstrating that B cells indeed do not induce a cytotoxic CD8\(^{+}\) T cell response via cross-presentation of Salmonella antigens from dead intracellular bacteria. This observation was confirmed by studying elimination of Salmonella-infected B cells by \(^{51}\)Cr-release (Fig. 5C). Together, these results show that B cells are not able to cross-present antigens of dead Salmonella and that Salmonella contributes to the activation of a Salmonella-specific cytotoxic CD8\(^{+}\) memory response.

**Discussion**

Studies in B-cell-deficient mice showed that protective immunity to Salmonella strongly depends on B cells [27]. This dependency does not only result from antibody generation, as passive transfer of Salmonella-immune serum cannot transfer resistance to Salmonella [28]. In addition, B cells are involved in the generation of a profound CD4\(^{+}\) and CD8\(^{+}\) T cell response after Salmonella infection [21], but the precise role of B cells remained unclear. We previously showed that human antigen-specific B cells that have internalized Salmonella via their BCR are able to induce a Salmonella-specific CD4\(^{+}\) T cell response which aids the humoral immune response against Salmonella [20]. The data described here may explain the role of B cells in the immune response against Salmonella infection other than antibody formation. In contrast to data in mouse B cell lines, in which uptake of Salmonella does not lead to antigen cross-presentation via MHC class I [29], we now demonstrate that Salmonella-specific human primary B cells that have phagocytosed Salmonella via their BCR are capable to induce a strong recall response of cytotoxic CD8\(^{+}\) T cells after cross-presentation of Salmonella antigens. We previously showed that in the human Ramos B cell line, Salmonella is not only capable to survive, but also to replicate intracellularly. In contrast, in primary human B cells Salmonella survives, but is unable to replicate inside the B cell [20]. A recent report shows that poor intracellular replication of Salmonella leads to reduced antigen presentation in DCs [30]. In contrast, we found that Salmonella-specific primary B cells are efficient in cross-presentation of Salmonella antigens from the non-replicating bacteria and activate Salmonella-specific CD8\(^{+}\) T cells that show a functional cytotoxic T cell response. Thus, primary human B cells are capable in cross-presentation of non-replicating Salmonella to CD8\(^{+}\) T cells.

After internalization by the B cell, Salmonella survives in the SCV. For cross-presentation, Salmonella-antigens should be loaded onto MHC class I. The TSS of Salmonella could play a role in delivery of antigens in the cytosol by injecting proteins directly into the cytosol [31]. These proteins can be degraded by the proteasome and after transportation into the ER, loaded onto MHC class I molecules. We demonstrated that both SPI-1 and SPI-2 contribute to cross-presentation, but are not individually required. It is therefore likely that antigens excreted in the host cytosol by SPI-1 and SPI-2 are both used for antigen processing to MHC class I. This is in line with the observation that B cells could not cross-present Salmonella-specific antigens of heat-killed Salmonella in which SPI-1 or SPI-2 are no longer active. Although the exact molecular pathways of cross-presentation in B cells remain to be elucidated, it is clear that Salmonella itself appears to be involved in the generation of an effective cytotoxic CD8\(^{+}\) T cell response against the bacteria upon B cell infection. This phenomenon points to the occurrence of co-evolution of bacterial immune evasion and the generation of effective anti-bacterial immunity.

Cross-presentation of Salmonella antigens by B cells leads to activation of a CD8\(^{+}\) cytotoxic T cell response, but help of CD4\(^{+}\) T cells is required. The main factor of CD4\(^{+}\) T cell help seems to be
IL-2, since replacement of CD4⁺ T cell help by addition of IL-2 is sufficient to elicit CD8⁺ T cell proliferation, induced by Salmonella infection of the B cells. The CD4⁺ dependency of the CD8⁺ response led us to investigate if the observed responses were in fact mere bystander activation. Proliferation upon restimulation of Salmonella-primed CD8⁺ T cells implies Salmonella-specificity of CD8⁺ T cell activation. In addition, the observations that CD8⁺ T cells activated by Salmonella-infected B cells specifically kill Salmonella-infected cells, but do not kill B cells infected with Staphylococcus or dead Salmonella, demonstrate that the CD8⁺ T cell response upon Salmonella-infection of autologous B cells is at least in part Salmonella-specific.

Various reports have described that B cells play a role in the expansion of Salmonella-specific T cells during reinfection, but less in the induction of CD8⁺ T cell responses in primary infection. The reason for this was not understood and has been attributed to the fact that antigen-specific B cells are probably the main B cell population with an antigen presenting function in Salmonella infection and that the frequency of antigen-specific B cells is elevated during a secondary infection (reviewed in [32]). Our data now show that indeed the antigen-specific B cells are the cells that are responsible for efficient cross-presentation of Salmonella antigens. In addition, our data provide an additional explanation why B cells are mainly involved in the recall response; Salmonella-infected B cells do not prime naive CD8⁺ T cells, but are very efficient in reactivation of cytotoxic CD8⁺ memory T cells. This implies that other APCs (e.g. DCs) are still needed to prime naive CD8⁺ T cells. This priming by DCs might occur via antigen-presentation after phagocytosis of Salmonella itself, or via uptake of apoptotic bodies from other Salmonella-infected DCs. In secondary infections however B cells now seem to enter the stage as important APCs for the execution of the CD8⁺ recall response. DCs can still induce CD8⁺ proliferation via direct infection or via suicide cross-presentation upon ingestion of infected apoptotic cells [22], but DCs were shown to mainly activate the T EM compartment [22]. In contrast, Salmonella-infected B cells efficiently activate the both the T CM and T EM compartments. This ensures not only the direct terminal differentiation of effector memory cells, but also the expansion of the Salmonella-specific CD8⁺ memory T cell compartment, which may both amplify the anti-Salmonella immune response and simultaneously ensure generation of anti-Salmonella memory for further reinfections.

In summary, we propose a model on the role of B cells in the generation of the humoral and cellular immune response against Salmonella. After infection, Salmonella enters the body via DCs. The DC-mediated route ensures CD4⁺ T cell activation but is less effective in CD8⁺ T cell activation [30]. The other part of entry for Salmonella is via M cells after which it encounters B cells, which are situated in the Peyer’s Patches, directly under the M cells. Salmonella-specific B cells internalize Salmonella via their BCR and are activated. Next, internalization of Salmonella leads to presentation of Salmonella antigens MHC class II molecules and activation of Salmonella-specific CD4⁺ T-helper cells that stimulate Salmonella-infected B cells to secrete Salmonella-specific antibodies [20], either locally or upon arrival or the infected B cells in the mesenteric lymph node. Upon re-infection, Salmonella-specific memory B cells ensure rapid antibody production but Salmonella-infected B cells also mediate a strong cytotoxic CD8⁺ recall response to eliminate infected cells. The Salmonella-specific CD4⁺ response that aided antibody production in early stages of the immune response is now also required for the activation of the cytotoxic memory T cell response against Salmonella. Thus, uptake of Salmonella by antigen-specific B cells may generate a survival niche for Salmonella, but at the same time it strongly contributes to the generation of effective anti-Salmonella immunity at multiple levels of the adaptive immune response.

Materials and Methods

Antibodies and fluorophores

mAb anti-human IgM (MH15, Sanquin, Amsterdam, The Netherlands) was mixed with rat anti-mouse IgG1 antibody (RM161.1, Sanquin) and mAb anti-S. typhimurium LPS (1E6, Biodies International, Kemenbunk, ME) to generate BCR-LPS tetramer antibody complexes, used to coat bacteria as previously described [20]. Antagonist anti-human CD40 mouse monoclonal antibody was a kind gift of Dr. L. Boon.

The following labeled anti-human mAbs were obtained from BD Biosciences (San Jose, CA): anti-IFN-γ-FITC, anti-CD27-PE, anti-CD107a-PE, anti-CD8-PerCP-Cy5.5, anti-CD4-APC, anti-CD45RO-PE, AnnexinV-APC and IgG1-PerCP-Cy5.5 isotype control. FITC-conjugated antibody IgG1, IgG2a and IgG2b, IgG1-PE, and IgG1-APC isotype controls and PE-conjugated anti-CD8 blocking antibody were obtained from DAKO (Glostrup, Denmark). Anti-CD45RA-FITC and anti-CD45RO-FTTC were obtained from Sanquin and DAPI from Sigma-Aldrich (Steinheim, Germany). CFSE (Invitrogen, Paisley, UK) labeling was used in proliferation assays.

Bacterial growth conditions

GFP expressing S. typhimurium SL1344 was described before [33]. GFP-Salmonella defective in SPI-1 (invA mutant) or SPI-2 (ssrA mutant) were a kind gift of M. Rescigno (European Institute of Oncology, Milan, Italy). Staphylococcus aureus expressing GFP (RN4220 with pWVW189GFP) was kindly provided by S. A. J. Zaat (Academic Medical Center, Amsterdam, The Netherlands). All bacteria strains were grown overnight at 37°C in Luria-Bertani (LB) broth with carbenicillin or chloramphenicol (Sigma-Aldrich, St Louis, MO) to maintain GFP expression while shaking, subcultured at a dilution of 1:33 in fresh LB medium and incubated while shaking at 37°C for 3 to 4 hours to obtain exponentially growing bacteria. For coating, bacteria were washed twice with PBS and incubated with BCR-LPS tetrameric antibody complexes for 30 minutes at room temperature and washed twice with PBS to remove unbound antibodies. For experiments with dead Salmonella, bacteria were heat killed by incubation at 65°C for 15 minutes.

Lymphocyte isolation and B lymphocyte infection with Salmonella

Human PBMCs were isolated by centrifugation on a Ficoll-Hypaque gradient (Axis-Shield PoC AS, Oslo, Norway) from a buffycoat obtained from healthy donors (Sanquin). All donors provided written informed consent in accordance with the protocol of the local institutional review board, the Medical Ethics Committee of Sanquin Bloodbank (Amsterdam, The Netherlands), and the Medical Ethics Committee of Sanquin approved the study. B and T cells were subsequently purified using anti-CD19, anti-CD4, anti-CD8 Dynabeads and DETACHaBEAD (Invitrogen), according to the manufacturer’s instructions. Monocytes were isolated by positive selection using CD14 microbeads and a magnetic cell separator (MACS, Miltenyi Biotec, Bergisch Gladbach, Germany). Monocytes were cultured at a concentration of 1×10⁵ cells/ml in 20 ml Cellgro medium (CellGenix, Freiburg, Germany) supplemented with GM-CSF (1,000 IU/ml; Cellgenix) and IL-4 (800 IU/ml; Cellgenix) in a 80 cm² cell culture flask (Nunc, Roskilde Denmark) to generate immature DCs. At day 6, the DCs were harvested and washed with antibiotic free medium.
B lymphocytes or immature DCs were incubated for 45 minutes at 37°C with \textit{Salmonella} without antibiotics. Next, cells were washed to remove unbound bacteria four times and cultured for 1 hour in medium containing 100 μg/ml gentamycin (Invitrogen) to eliminate non-phagocytosed bacteria. Cells were washed and cultured in RPMI 1640 medium with 10% FCS (Lonza, Basel, Switzerland), supplemented with 5% FCS (Bodinco, Alkmaar, The Netherlands), 100 μU/ml penicillin, 100 μg/ml streptomycin, 2 mM L-Glutamine, 50 μM 2-ME, 20 μg/ml human apotransferrin (Sigma-Aldrich), depleted for human IgG with protein G sepharose (Amersham, Uppsala, Sweden) and 10 μg/ml gentamycin.

Flow cytometry

Unless described otherwise, 1*10^5 \textit{Salmonella}-infected cells were cultured with 5*10^4 CFSE-labeled T cells (CD8^+ T cells alone or in a 1:1 ratio with CD4^+ T cells) for 6 days to activate and expand \textit{Salmonella}-specific T cells. 50,000 events were acquired on a LSR II (BD) and analyzed with FACSDiva software (BD). To test plasma membrane markers, 1*10^5 B cells with 5*10^4 T cells were cultured for 6 days and after addition of 10 IU/ml IL-2 (Chiron, Emeryville, CA) for another 6 days. All plasma membrane stainings were performed for 15 minutes at room temperature and washed after each incubation with PBS containing 0.1% BSA. 50,000 events were acquired on a LSR II (BD) and analyzed with FACSDiva software (BD). Lymphocytes were gated by forward and side scatter. Dead cells were excluded based on their positive reaction to DAPI staining. For some experiments, naïve T cells were sorted as CD8^+ CD45RA^+ CD45RO^− (T_N) and memory T cells as CD8^+ CD45RA^− CD45RO^+ (T_EM) and CD8^+ CD45RO^+ CD27^− (T_EM) and CD8^+ CD45RO^+ CD27^+ (T_EM) cells. Populations were >98% purified.

TCR clonality

CFSE labeled CD8^+ T cells were stimulated with \textit{Salmonella}-infected B cells or with anti-CD3 (1XE, 1 μg/ml) and anti-CD28 antibodies (CLB.CD28/1, 1 μg/ml). Proliferating and non-proliferating cells were sorted and DNA was isolated using QIAamp DNA Mini Kit, according to the manufacturer’s instructions (Qiagen, Valencia, CA). Next, TCR beta clonality was measured using the In Vivo Scribe TCRB Gene Clonality Assay for gel detection, according to manufacturer’s instructions (San Diego, CA).

Intracellular cytokine staining

B cells and T cells were cultured for 12 days, and 10 IU/ml IL-2 was added at day 6 for T cell survival. Cytokine production was measured by intracellular staining after restimulation with 0.1 μg/ml PMA, 1 μg/ml ionomycin and 10 μg/ml brefeldin A (Sigma-Aldrich) for 5 hours. Cells were washed twice with PBS, fixed with 1% formaldehyde (Merck, Darmstadt, Germany) for 15 minutes and after washing twice with PBS, permeabilized with 0.5% saponin (Calbiochem, CA) in PBS containing 1% BSA (Sigma-Aldrich) and incubated with fluorescent antibodies for 30 minutes at room temperature. 50,000 events were acquired on a LSR II (BD) and analyzed with FACSDiva software (BD).

CD8^+ degranulation assay

CD8^+ T cells were primed by 6 day incubation of 1*10^5 \textit{Salmonella}-infected B cells with 2.5*10^4 CD4^+ T cells and 2.5*10^4 CD8^+ T cells. The dividing T cells (CD8^+ CFSE^−) were FACs sorted after 6 days on a MoFlo Sorter (Dakocyotmaton, Glostrup, Denmark) and cultured with 50 IU/ml IL-2 for 6 more days. Next, isolated autologous B cells were thawed and infected with \textit{Salmonella}. For proteasome inhibition, MG-132 (Sigma-Aldrich) was added at a concentration of 20 μM before incubation with bacteria, and after infection, the cells were cultured overnight in the presence of the inhibitor. Next, the cells with proteasome inhibitor were irradiated (30 Gy) to prevent further initiation of antigen presentation after washing the cells to remove the proteasome inhibitor. Cells were not irradiated in other experiments in which no proteasome inhibitor was used. \textit{Salmonella}-infected B cells were incubated in medium containing 10 μg/ml gentamycin for 15 hours at 37°C to allow processing and presentation of \textit{Salmonella} antigens. Subsequently, the B cells were incubated at 37°C for 5 hours together with the primed \textit{Salmonella}-specific CD8^+ T cells in a ratio of 4:1, in the presence of anti-CD107a-PE labeled antibodies. Cells were washed twice with wash buffer (1 mM HEPES, 0.15 M NaCl, 5 mM KCl, 1.8 mM CaCl_2, 1 M MgCl_2, 0.1% BSA) and stained for CD8 and AnnexinV. After washing twice with washing buffer, DAPI was added and CD8^+ T cells were analyzed for CD107a expression. 50,000 events were acquired on a LSR II (BD) and analyzed with FACSDiva software (BD).

\[51^Cr\] release assay

\textit{Salmonella}-specific CD8^+ T cells were activated and FACs sorted as described and expanded with 50 IU/ml IL-2. Autologous B cells were thawed and infected with \textit{Salmonella}. After 15h, B cells were labeled with \( ^{51} \text{Cr} \) (105 MBq/ml, Perkin Elmer, Boston, MA) for 45 minutes at 37°C. After washing, the B cells were incubated in a 96-wells U-bottom plate (Costar Corning Inc., NY) with primed CD8^+ T cells in a 1:2 ratio. Incubation in medium or in Triton X-100 (1% final concentration; Merck) was used to determine spontaneous and maximum \( ^{51} \text{Cr} \) release, respectively. \( ^{51} \text{Cr} \) release was measured in the supernatant using filters with a gamma counter (Cobra II, Canberra Packard, Mississauga, Canada). The percentage of specific cell lysis was calculated using the following formula:

\[
\% \text{ specific lysis} = \frac{\text{[experimental release (cpm) – spontaneous release (cpm)]/maximal release (cpm) – spontaneous release (cpm)]} \times 100\%
\]

Statistical analysis

Statistical differences were determined by a paired Student’s t test, using GraphPad Prism (version 5.01, GraphPad Software, San Diego, CA).

Supporting Information

Figure S1 Blocking IL-2 or blocking CD8 reduces \textit{Salmonella}-infected B cell mediated CD8^+ T cell proliferation. \textit{Salmonella}-infected B cells were cocultured with CFSE labeled CD8^+ T cells and CD4^+ T cells, in presence of IL-2 blocking antibodies or CD8 blocking antibodies. CD8^+ T cell proliferation was measured after 6 days. Data shown are from one representative experiment of two independent experiments with different donors.

Figure S2 Uptake of \textit{Salmonella} by B cells and DCs. B cells (upper panel) or DCs (lower panel) were naturally infected with GFP expressing \textit{Salmonella} (Sal*, left) or infected with anti-IgM coated \textit{Salmonella} (Sal, right). \textit{Salmonella}-GFP positive cells were analyzed 1 hour after infection. Data shown are from one representative experiment of two independent experiments with different donors.
