Cell Reports 2016; 15:1757–1770
Abstract

Natural killer (NK) cells possess potent cytotoxic mechanisms that need to be tightly controlled. We here explored the regulation and function of GPR56/ADGRG1, an adhesion G protein-coupled receptor implicated in developmental processes and expressed distinctively in mature NK cells. Expression of GPR56 was triggered by Hobit, a homolog of Blimp-1, and declined upon cell activation. Through studying NK cells from polymicrogyria patients with disease-causing mutations in the ADGRG1 gene, encoding GPR56, and NK-92 cells ectopically expressing the receptor, we found that GPR56 negatively regulates immediate effector functions, including production of inflammatory cytokines and cytolytic enzymes, degranulation, and target cell killing. GPR56 pursues this activity by associating with the tetraspanin CD81. We conclude that GPR56 inhibits natural cytotoxicity of human NK cells.
Introduction

Natural killer (NK) cells are innate lymphoid cells that develop, mainly in the bone marrow, through a series of distinct phenotypic stages before they enter the circulation to specifically eradicate virus-infected and transformed cells (Freud and Caligiuri, 2006). Upon target cell encounter, differentiated CD56dim NK cells produce large amounts of cytokines, chemokines, and cytolytic proteins, similar to effector-type CD8+ T cells (Fauriat et al., 2010; Nagler et al., 1989; Vivier et al., 2008). The activity of cytotoxic CD56dim NK and CD8+ T cells is regulated by a comprehensive repertoire of activating and inhibitory receptors, including immunoglobulin-like receptors and C-type lectins (Lanier, 2008; Pegram et al., 2011).

G protein-coupled receptors (GPCRs) guide numerous cellular processes, including development and differentiation (Pierce et al., 2002), yet, in the immune system, they have been linked primarily with chemotaxis (Walzer and Vivier, 2011). Others and we recently showed that human cytotoxic lymphocytes, including CD56dull NK cells and CD27–CD45RA+ T cells, express the adhesion family GPCR (aGPCR) GPR56/ADGRG1 (Chiesa et al., 2010; Peng et al., 2011). Expression of GPR56 correlated closely with production of the cytolytic proteins perforin, granzyme A, and granzyme B and was not found in non-cytotoxic lymphocytes or myeloid cells. aGPCRs possess an N-terminal fragment (NTF) and a C-terminal fragment (CTF) that arise from autocatalytic cleavage at a GPCR-autoproteolytic site (GPS), embedded in a juxtamembranous GPCR autoproteolysis-inducing (GAIN) domain (Araç et al., 2012; Lin et al., 2004). At the cell surface, the NTF remains non-covalently attached to the CTF, giving rise to a characteristic bipartite structure with the two fragments being engaged in distinct activities (Langenhan et al., 2013). The NTF of GPR56 binds transglutaminase and collagen III, while the CTF recruits Ga proteins leading to activation of RhoA (Ras homolog gene family member A) and mTOR (mechanistic target of rapamycin) pathways (Ackerman et al., 2015; Giera et al., 2015; Iguchi et al., 2008; Little et al., 2004; Luo et al., 2011; Paavola et al., 2011; White et al., 2014; Xu et al., 2006).

We here tested the relation of GPR56 with the differentiation, activation, and function of human NK cells. We provide evidence that GPR56 expression is triggered by the transcriptional repressor Hobit (homolog of Blimp-1 in T cells), is downregulated upon cellular activation, and inhibits immediate effector functions, including inflammatory cytokine and cytolytic protein production, degranulation, and target cell killing. We conclude that GPR56 is a differentiation marker and inhibitory receptor on human NK cells.
Chapter 7

Results

Hobit, the human homolog of Blimp-1 in T cells, drives expression of GPR56 in non-dividing, fully differentiated human NK cells

GPR56 is expressed by all human cytotoxic lymphocytes, including CD56dim NK cells (Chiesa et al., 2010; Peng et al., 2011). Upon stimulation with common gamma chain cytokines, such as interleukin (IL)-2, proliferating NK cells lose expression of GPR56 (Chiesa et al., 2010) (Figure 1A). IL-2-dependent cytotoxic NK-92 cells weakly express GPR56. IL-2 withdrawal stopped NK-92 cell division, leading to cell cycle arrest in the G1 phase and surface expression of GPR56 (Figure 1B). Of note, IL-2 deprivation caused upregulation of surface markers commonly associated with terminal cell differentiation, such as KLRG1 (killer cell lectin-like receptor subfamily G member 1) and B3GAT1 (galactosylgalactosylxylosylprotein 3-beta-glucuronosyltransferase 1), the enzyme that generates the CD57 glycosylation epitope, and downregulation of the cell exhaustion marker PD1 (programmed cell death 1) (Figure 1C). These changes correlated with altered expression of transcription factors involved in effector lymphocyte development, such as Blimp-1 (B lymphocyte-induced maturation protein-1), Bcl-6 (B-cell lymphoma 6), T-bet (T-box expressed in T cells), Eomes (eomesoderm), and the recently identified Hobit (homolog of Blimp-1 in T cells) (van Gisbergen et al., 2012; Vieira Braga et al., 2015) (Figure 1C). In line with their in part contrary activities (Crotty et al., 2010; Daussy et al., 2014; Knox et al., 2014), downregulation of Blimp-1 and T-bet was accompanied by upregulation of Bcl-6 and Eomes, respectively. The most prominent change, with a ~25-fold induction, occurred with Hobit.

We next correlated GPR56 protein expression with the presence of various surface makers, cytolytic proteins, and transcription factors in primary NK cells. In line with its absence on immature CD56high NK cells, we detected almost no GPR56 on NK cells from tonsil (data not shown). In contrast, mature circulating NK cells commonly expressed GPR56. GPR56 was acquired prior to the late differentiation/senescence markers KLRG1 and CD57 (Björkström et al., 2010; Lopez-Vergès et al., 2010), as most clearly exemplified by cells from cord blood (Figure 1D). In line with the uniform presence of GPR56 on CD56dim NK cells, no association was found with the expression of activating or inhibitory natural cytotoxicity receptors (NKp30, NKp44, NKp46), NK-cell receptors (NKGe2a, NKGe2c, NKGe2d), and killer immunoglobulin-like receptors (KIR2DL1/S1, KIR2DL2/L3, KIR3DL1) (Figure S1). Supporting previous findings (Peng et al., 2011), the presence of GPR56 correlated with production of the cytolytic mediators perforin and granzyme B (Figure S1). Cells expressing GPR56 were positive for the transcription factors T-bet, Eomes, and Hobit; in particular, expression of GPR56 and Hobit was strongly associated (Figure 1D). Thus, non-dividing, fully differentiated NK cells, found in the circulation and commonly indicated as CD56dim cells, express GPR56 in a distinctive manner.

Recent studies identified a subset of long-lived memory-like NK cells, associated with prior human cytomegalovirus infection, that can mount long-term effective recall responses (Lee et al., 2015; Schlums et al., 2015; Zhang et al., 2013). We found that these memory-like NK cells, which can be distinguished by low presence of the transcription factor PLZF (promyelocytic leukemia zinc finger) and lack of FcRy
The Adhesion G Protein-Coupled Receptor GPR56/ADGRG1 Is an Inhibitory Receptor on Human NK Cells

Figure 1. Hobit drives the expression of GPR56 in non-dividing, fully differentiated NK cells. (A) Expression of GPR56 and CD57 on proliferating CD56+CD3– NK cells was measured using CFSE dilution after 6 days of stimulation with 50 U/ml IL-2. Flow cytometry plots of one representative experiment (left) and quantification of the mean percentage of proliferating cells (right). (B) NK-92 cells were incubated with or without 50 U/ml IL-2 for 18 h and analyzed for cell cycle and expression of GPR56 and CD57 by flow cytometry (left). Quantification of percentages of cells in G1, S, and G2/M phase, and relative geoMFI of GPR56 and CD57 expression, compared to isotype controls (right). (C) Quantification of mRNA expression of surface receptors and transcription factors by RT-PCR in NK-92 cells, incubated with or without 50 U/ml IL-2 for 18 h. (D) Protein expression of surface makers and transcription factors by CD56+CD3– NK cells in cord blood and peripheral blood in relation to GPR56 expression, measured by flow cytometry. (E) Expression of GPR56 on long-lived memory-like NK cells, defined by absent/
low expression of FcRy and PLZF, determined by flow cytometry. (F-H) NK-92 cells overexpressing scrambled shRNA, Eomes shRNA, or Hobit shRNA were incubated with or without 50 U/ml IL-2 for 18 h and analyzed by flow cytometry for expression of Eomes, Hobit, and GPR56. Representative flow cytometry plots (F), quantification of Hobit and GPR56 protein expression, compared to isotype controls, by flow cytometry (G), and quantification of mRNA expression of GPR56 by RT-PCR (H). (I-K) Parental Jurkat cells and Jurkat cells overexpressing Flag-tagged vector control or Hobit were incubated with 10 µg/ml doxycycline for 48 h and analyzed by flow cytometry for expression of GPR56. Representative flow cytometry plots (I), quantification of Flag and GPR56 protein expression, compared to isotype controls, by flow cytometry (J), and quantification of mRNA expression of GPR56 by RT-PCR (K). All data are means ± SEM of 3-5 independent experiments. *p<0.05, **p<0.01, ***p<0.005

(high-affinity IgE receptor, γ subunit), express GPR56 (Figure 1E). The T-box transcription factor Eomes (eomesodermin) is crucially involved in effector lymphocyte differentiation and, like GPR56, is expressed in differentiating neurons in the developing human brain (Elsen et al., 2013). Intriguingly, lack of Eomes causes a microcephaly syndrome (Baala et al., 2007) similar to the malformation seen in patients with null GPR56 expression (Piao et al., 2004). To test a causal relationship between Eomes and the expression of GPR56, we applied shRNA knockdown of EOMES in NK-92 cells. Reduced Eomes expression did not prevent GPR56 induction upon IL-2 withdrawal (Figure 1F). In contrast, knockdown of ZNF683, encoding Hobit, largely prevented GPR56 induction in NK-92 cells cultured without IL-2 (Figure 1F-H). Furthermore, ectopic expression of Hobit in Jurkat cells, which express neither GPR56 nor Hobit, induced expression of GPR56 (Figure 11-K), indicating that Hobit drives the expression of GPR56 in human lymphocytes.

**GPR56-deficient BFPP patients have normally developed but functionally elevated NK cells**

Loss-of-function mutations in ADGRG1, encoding GPR56, cause a severe cortical malformation, known as bilateral frontoparietal polymicrogyria (BFPP) (Piao et al., 2004; 2005). To test whether defective expression of GPR56 would affect NK-cell differentiation and/or function, we studied two unrelated pairs of BFPP siblings bearing the mutations 1693C>T (R565W) and 1036T>A (C346S), respectively. Previous in vitro analysis revealed that both mutations strongly reduce surface expression of GPR56 (Chiang et al., 2011; Jin et al., 2007). We found that the R565W mutation abolished GPR56 expression on NK (and T) cells completely, whereas the C346S mutation reduced surface levels of GPR56 by about 20-fold (Figure 2A, Figure S2, and data not shown). All patients had normal numbers of circulating NK cells (Figure 2A and data not shown). Moreover, their NK cells had a fairly normal phenotype, based on the expression of surface markers, including receptors with activating or inhibiting effector functions, cytolytic proteins, and transcription factors (Figure 2A, Figure S2, and data not shown). However, CD56dim NK cells in the R565W patients, which completely lacked GPR56, expressed lower levels of CD94 expression, indicating maturation. Moreover, the cells expressed less/no inhibitory KIR2DL1/S1, while steady-state expression of cytolytic enzymes was unchanged (granzyme B) or even marginally reduced (perforin).

The phenotypic changes found in CD56dim NK cells in the 1693C>T (R565W) siblings raised the possibility that the cytolytic capacity of NK cells in these patients was altered. Indeed, their NK cells killed K562 cells more efficiently than control

cells, as indicated by enhanced degranulation (CD107a expression) and induction of apoptosis in the target cells. In addition, target cell contacts resulted in enhanced production of tumor necrosis factor (TNF) and interferon (IFN)γ by GPR56-deficient NK cells (Figure 2B,C). Thus, lack of GPR56 did not hamper normal NK-cell development, but appeared to enhance their functional capacity.
Upon encounter of virus-infected or transformed cells, NK cells downregulate inhibitory receptors to acquire maximal killing capacity (Pegram et al., 2011). PMA (phorbol-12-myristate-13-acetate) stimulation downregulates ectopic GPR56 in monocytic U937 cells (Little et al., 2004). In primary NK cells, PMA treatment resulted in loss of GPR56 at concentrations as low as 0.01 ng/ml, which was enhanced by ionomycin (data not shown, Figure 3A, and Figure S3A). With a loss of >60% of cell surface GPR56 within 10 min and >80% after 2 h, kinetics resembled the downregulation
The Adhesion G Protein-Coupled Receptor GPR56/ADGRG1 Is an Inhibitory Receptor on Human NK Cells

Studies with pharmacological inhibitors confirmed the involvement of protein kinase (PK)C, but not MAP kinases, in PMA-induced GPR56 downregulation (Figure S3B). Activation of PKA with forskolin did not affect GPR56 surface levels (Figure S3A).

agPCRs are downregulated by internalization or shedding (Karpus et al., 2013; Langenhan et al., 2013). The dynamin inhibitor dynasore that prevents internalization...
and GM6001, a broad-spectrum matrix metalloproteinase (MMP) inhibitor, synergistically blocked the downregulation of GPR56 upon PMA stimulation (Figure 3C). In contrast, downregulation of CD16 upon PMA stimulation was primarily blocked by GM6001 (Figure S3C). Cleavage of CD16 involves a disintegrin and metalloproteinase (ADAM)17, expressed in NK cells (Romee et al., 2013). Indeed, two ADAM17 inhibitors affected PMA-induced downregulation of CD16, but not GPR56 (Figure S3C). NK cells pre-incubated with fluorescently labeled anti-GPR56 or anti-CD16 monoclonal antibodies (mAbs) on ice and subsequently treated with PMA for 2 h had lost ~10% of the GPR56-bound mAb, but ~70% of the CD16-bound mAb, indicating that GPR56 was partially endocytosed from the cell surface (Figure 3D). Moreover, an increase in soluble GPR56 in the medium was detected after NK-cell stimulation with PMA, which was abrogated by inhibitors of PKC and MMPs (Figure 3E). Thus, PKC activation induces downregulation of GPR56 in primary NK cells via internalization and shedding.

Physiological activation of primary NK cells occurs through pro-inflammatory cytokines, crosslinking of activating receptors, or exposure to target cells. To test the effect of cytokines, we incubated peripheral blood mononuclear cells (PBMCs) for 12–24 h with IL-2, IL-15, or IL-18, alone or in combination. A combination of IL-15 and IL-18 reduced GPR56 surface levels by ~40% after 12 h and by ~70% after 24 h, which was more efficient as compared to the downregulation of CD16 by these cytokines (Figure 3F). Inhibition of PKC and MMPs blocked the downregulation of GPR56 and CD16, while blockade of endocytosis with dynasore had no effect (Figure 3G). In line with our former data, inhibition of ADAM17 blocked the downregulation of CD16, but not GPR56, leaving the identity of the sheddase that releases the NTF of GPR56 open (data not shown). Crosslinking CD16 or exposure to K562 had a small effect on GPR56 surface expression (data not shown). In sum, physiological NK-cell activation through cytokines causes downregulation of GPR56 by shedding of the NTF of the receptor.

Notably, activation of primary NK cells downregulates the expression of Hobit. In PBMCs stimulated for 2 h with PMA or for 12–24 h with cytokines, we found a clear decrease in Hobit and GPR56 transcript levels (Figure 3H), indicating that NK-cell activation causes downregulation of GPR56, immediately, by shedding of the NTF (see above), and permanently, by terminating gene expression.

**GPR56 controls NK-cell effector functions**

To further examine the role of GPR56 in NK-cell function, we applied ectopic GPR56 expression in NK-92 cells (Peng et al., 2011). Proper expression and auto-proteolytic modification of the receptor were confirmed by flow cytometry and Western blot analysis, respectively (Figure S4A). GPR56 overexpression did not affect cell growth (Figure S4B,C). Quantification of cytolytic proteins revealed a much-reduced expression of granzyme B, both at the transcript and protein level, in NK-92–GPR56 cells (Figure 4A,B). In contrast, mRNA and protein levels of perforin were comparable between NK-92–Neo and NK-92–GPR56 cells. Moreover, a lower level of TNF but not IFNγ transcript was detected in NK-92–GPR56 cells (Figure 4C). When activated by PMA, NK-92–GPR56 cells produced less TNF and IFNγ than NK-92–Neo cells (Figure 4D,E). These results suggested that forced GPR56 expression in NK-92 cells nega-
Figure 4. GPR56 expression in NK-92 cells reduces cytotoxic capacity. Vector-transduced (Neo) and GPR56-overexpressing NK-92 cells were studied. (A,B) Quantification of mRNA and protein expression of the cytolytic enzymes perforin and granzyme B by RT-PCR (A) and flow cytometry (B) in NK-92–Neo and NK-92–GPR56 cells. (C,D) Quantification of mRNA and protein expression of the cytokines TNF and IFNγ by RT-PCR (C) and flow cytometry (D) in NK-92–Neo and NK-92–GPR56 cells. Protein expression was determined after stimulating cells with 10 nM PMA for 3 and 6 h. (E) Secretion of TNF and IFNγ by NK-92–Neo and NK-92–GPR56 cells cultured with K562 target cells for 1, 3, and 6 h, measured by ELISA. (H) Secretion of TNF and IFNγ by NK-92–Neo and NK-92–GPR56 cells cultured with K562 target cells for 1, 3, and 6 h, measured by ELISA. tively regulates the expression of effector molecules. Hence, we examined various NK-cell effector activities, including target cell conjugation and killing, degranulation, and cytokine production (both intracellular and secreted). GPR56 significantly attenuated cytotoxicity against K562 cells, as indicated by reduced target cell apoptosis, NK-cell degranulation, and production of TNF and IFNγ, when compared with NK-92–Neo cells (Figure 4F-H). The compromising effects of GPR56 on NK-cell cytotoxicity were also observed when NK-92–GPR56 cells were incubated with target cells more resistant to cell conjugation and killing, such as THP-1 and HeLa cells (Figure S5). Taken together, we concluded that GPR56 expression in NK-92 cells attenuates cytotoxic capacity, in accordance with the findings derived from the primary NK cells of BFPP patients.
Figure S4. GPR56 overexpression does not affect proliferation of NK-92 cells. (A) Stable over-expression of GPR56 in NK-92 cells, confirmed by flow cytometry, using mAb CG4 (left), and by Western blot analysis of whole cell lysates, using mAb CG4 (right). β-actin was detected as loading control. (B) Growth curve of vector-transduced (Neo) and GPR56-overexpressing NK-92 cells. (C) Quantification of the percentage of vector-transduced and GPR56-overexpressing NK-92 cells in G1, S, and G2/M phase, analyzed by flow cytometry.

GPR56 complexes with CD81 to negatively regulate NK-cell effector functions

aGPCRs possess a characteristic bipartite structure (Hamann et al., 2015). Notably, target cell killing was also reduced in NK-92 cells expressing cleavage-deficient GPR56, indicating that autocatalytic processing at the GPS is not a prerequisite for the inhibitory activity of GPR56 in NK cells (Figure S6). Moreover, we could not confirm interaction with collagen III, the binding partner of GPR56 on neuronal cells (Luo et al., 2011) (Figure S7). These findings are in line with reports showing that the CTF of GPR56 can signal independently of the NTF (Paavola et al., 2011; L. Yang et al., 2011).

The CTF of GPR56 forms complexes with the tetraspanin proteins CD9 and CD81 at the cell surface (Little et al., 2004). CD81 has been previously reported to inhibit human NK-cell functions, when crosslinked by the major hepatitis C virus (HCV) envelope protein E2 or anti-CD81 mAbs (Crotta et al., 2002; Tseng and Klimpel, 2002). Flow-cytometric analysis showed significant amounts of CD81, but little CD9, in NK-92 cells. Interestingly, GPR56 overexpression strongly lowered CD81 protein levels, even though RNA transcript levels were reduced only slightly (Figure S8A), which might be explained by a relatively high turnover of GPR56 (and complexed CD81) in NK-92–GPR56 cells (data not shown). Western blotting indicated that NK-cell activation by PMA reduced GPR56 protein levels without affecting CD81, but interaction with K562 target cells diminished the levels of both GPR56 and CD81 (Figure S8B).

On the other hand, no significant changes in CD81 protein levels were observed when NK-92–Neo cells were activated by PMA or by interaction with K562 cells (Figure S8B). This result suggested that NK-92–K562 cell interaction might cause dynamic changes of the GPR56–CD81 complex on the cell surface. Indeed, confocal immunofluorescence microscopy revealed marked redistribution of GPR56 and CD81 in NK-92–GPR56 cells before and after target cell conjugation (Figure 5A). At steady state, GPR56 and CD81 were largely co-localized and distributed homogenously on the cell surface. After conjugation with K562 cells, the levels of both GPR56 and CD81 were reduced, and the two receptors were clustered mostly to areas resembling immune synapses, where granzyme B also accumulated (Figure 5A). Such reduction and clustering of CD81 protein was not observed in NK-92–Neo cells, suggesting a critical role for GPR56 in this process.

We confirmed the formation and reduction of GPR56–CD81 complexes in NK-92–K562 co-cultures by (immunoprecipitation) IP and IP–re-IP experiments (Figure 5B). CD81 was readily detected in NK-92–GPR56 cell lysate immunoprecipitated with the anti-GPR56 CG2 mAb. Critically, the amount of precipitated CD81 was comparable in the lysate of resting and PMA-activated NK-92–GPR56 cells, but much reduced in the same cells co-cultured with K562 cells. This result was further verified by IP with the anti-CD81 mAb first, followed by re-IP with anti-GPR56 CG2 mAb (Figure 5B). These results indicated that GPR56 indeed associates with CD81 and that the GPR56–CD81 complexes are diminished upon NK-cell interaction with target cells.

To delineate how the GPR56–CD81 complex modulated NK-cell function, anti-GPR56 mAbs were employed. Cross-linking of GPR56 by mAb ligation with CG2 and CG5, but not CG3, caused a rapid dissociation of the GPR56–CD81 complex as shown by the IP experiments (Figure 5C and Figure S9). Importantly, the cytolytic function
Figure 5. GPR56-CD81 complexes at the immune synapse repress cytotoxicity and cytokine production of NK cells. (A) Surface CD81 and GPR56, and intracellular granzyme B of NK-92–K562 cell conjugates were sequentially stained and detected using confocal microscopy. DAPI staining defined the morphology of nuclei. Scale bars, 10 μm. (B) 1% CHAPS cell lysate was immunoprecipitated with either anti-GPR56 or anti-CD81 mAb, as indicated. The presence of GPR56, CD81, and CD9 was revealed by immunoblotting (IB) using specific mAbs. (C) NK-92–GPR56 cells were incubated in the absence (untreated) or presence of 10 μg/ml of GPR56 mAbs at 37°C or 0°C for 15 min before lysate collection for IP using anti-GPR56 mAb. Mouse IgG1 was used as an isotype control. The presence of CD81 in each immunoprecipitate was revealed by immunoblotting. (D-G) NK-92–GPR56 (D,F) or human primary NK cells (E,G) were incubated in plates pre-coated with or without various anti-GPR56 mAbs (10 μg/ml) as indicated for 2 h before adding K562 target cells. Percentage of dead target cells in each sample was quantified by flow cytometric analysis following 4 h of co-culture (D,F), and amount of TNF and IFNγ released into medium during 6 h incubation was measured by ELISA (E,G). Data are representative of 3 independent experiments; values indicate the mean ± SEM. ***p<0.005
The Adhesion G Protein-Coupled Receptor GPR56/ADGRG1 Is an Inhibitory Receptor on Human NK Cells

Figure S6. Suppression of cytotoxicity of NK-92 cells does not require autocatalytic processing of GPR56. Figure S7. Collagen III does not bind GPR56 on NK-92–GPR56 cells. (A,B) NK-92 and K562 cells overexpressing GPR56 were incubated with 10 µg/ml FITC-conjugated collagen I or III for 30 min and analyzed by flow cytometry for ligand binding. K562 cells overexpressing human (h) and mouse (m) LAIR were used to confirm collagen binding (Lebbink et al., 2006). FITC-conjugated collagen III also did not stain PBMCs (data not shown). Data are means ± SEM of 3 independent experiments.

and cytokine (TNF and IFNγ) secretion of NK-92–GPR56 and human primary NK cells were greatly enhanced in the presence of CG2 or CG5 mAbs, whereas the isotype control Ab and CG3 mAb failed to show such an effect (Figure 5D-G). Similarly, shRNA knockdown of CD81 restored K562 target cell killing by NK-92–GPR56 cells (Figure S10). Finally, we tested whether Gαq/11, which has been implicated in GPR56–CD81 complex signaling (Little et al., 2004), is required. Of note, a novel, highly selective Gαq/11 inhibitor (FR900359) did not restore cytolytic activity in NK-92–GPR56 cells (data not shown). We concluded that association with CD81, but not Gαq/11 signaling, is crucial for the ability of GPR56 to inhibit NK-cell functions.
Figure S8. Cell activation and cross-linking of GPR56 with specific mAbs modulates GPR56–CD81 complexes in NK-92–GPR56 cells. (A) Expression of CD81 and CD9, analyzed by flow cytometry (left panel) and RT-PCR (right panel). (B) Western blot analysis of expression of GPR56, CD81, and CD9 in NK-92–Neo and NK-92–GPR56 cells. NK-92 cells were either stimulated with PMA or activated by target cells (effector/target cell ratio=1/2) for 1 h, as indicated. 1% CHAPS extract collected from 2x10^5 equivalents of K562 and 1x10^5 equivalents of NK-92 cells were loaded in each lane and analyzed by Western blotting using anti-GPR56, anti-CD81, and anti-CD9 mAbs. One of two comparable experiments is shown.

Figure S9. Cross-linking of GPR56 by mAb ligation rapidly dissociates the GPR56–CD81 complex. NK-92–GPR56 cells were pre-treated with 10 ug/ml of CG2 for the indicated times from 0 to 20 min before lysate collection for IP using anti-GPR56 mAb CG2. Mouse IgG1 was used as an isotype control. Mouse IgG1 was used as an isotype control. The presence of CD81 in each immunoprecipitate was revealed by immunoblotting.
The Adhesion G Protein-Coupled Receptor GPR56/ADGRG1 Is an Inhibitory Receptor on Human NK Cells

Figure S10. Knockdown of CD81 restores effector functions of GPR56.
(A,B) NK-92–Neo and NK-92–GPR56 cells transduced with scrambled shRNA or CD81 shRNA were analyzed for expression of CD81. Quantification of mRNA expression by RT-PCR (A) and representative flow cytometry plots (B). (C) NK-92–Neo and NK-92–GPR56 cells transduced with scrambled shRNA or CD81 shRNA were incubated with fluorescently labeled or unlabeled K562 target cells for 5 h and analyzed for K562 cell death, NK-cell degranulation (CD107a), and intracellular production of TNF and IFNγ. All data are means ± SEM of 3 independent experiments.

Figure S11. Inhibition of NK-cell cytotoxicity by GPR56 does not require Gαq/11.
NK-92–Neo and NK-92–GPR56 cells, pretreated with 1 µM FR900359 (inhibits Gαq/11) or 25 µM Y27632 (inhibits ROCK) for 5 h, were incubated with fluorescently labeled or unlabeled K562 target cells for 5 h and analyzed by flow cytometry for K562 cell death, NK-cell degranulation (CD107a), and intracellular production of TNF and IFNγ. All data are means ± SEM of 6 independent experiments.
Discussion

We here describe GPR56 as a novel inhibitory receptor expressed by human CD56dim NK cells. CD56dim NK and CD27–CD45RA+ T cells are highly reactive cytotoxic effector lymphocytes that protect the body against harmful viruses and neoplasms. The effective cytotoxicity, displayed by these cells, requires a tight interplay between activating and inhibiting control mechanisms (Caligiuri, 2008). We previously reported that cytotoxic human lymphocytes, in contrast to non-cytotoxic lymphoid or myeloid blood cells, express GPR56 (Peng et al., 2011). This study extends these findings by showing that GPR56 is induced in CD56dim NK cells prior to the upregulation of KLRG1 and CD57, which both appear at later stages of differentiation, associated with terminal differentiation (Björkström et al., 2010; Lopez-Vergés et al., 2010; Voehringer et al., 2002). Of note, long-lived memory-like NK cells, defined by absent/low expression of FcRy and PLZF (Lee et al., 2015; Schlums et al., 2015; Zhang et al., 2013), also expressed GPR56. GPR56 seems to be the best currently available surrogate surface marker to indicate cytolytic capacity across all lymphocyte subsets. The restricted expression of GPR56 by only CD56dim NK (and CD27–CD45RA+ T) cells indicates tight control of its induction and regulation at the transcript and protein level. We obtained evidence that expression of GPR56 is induced by Hobit, a close relative of Blimp-1, recently discovered by us (van Gisbergen et al., 2012). In humans, Hobit is expressed in quiescent effector NK and T cells, very closely matching the expression of GPR56 (Vieira Braga et al., 2015). Implying a causal relationship, Hobit knockdown in NK-92 cells prevented induction of GPR56 upon IL-2 withdrawal, and ectopic Hobit enabled GPR56 expression in Jurkat T cells. In contrast, manipulating the expression of Eomes did not affect GPR56 expression, despite its prominent role in the differentiation and maturation of effector NK and T cells and, like GPR56, its expression in developing neurons and relationship with polymicrogyria (Baala et al., 2007). Thus, on current evidence, GPR56 is a transcriptional target of Hobit in human NK and T cells.

Of note, the GPR56 locus has 17 transcriptional start sites in humans, which are targets of different transcription factors, such as peroxisome proliferator-activated receptor gamma co-activator 1-alpha 4 (PGC-1α4) in muscle cells (White et al., 2014) and so-called heptad complex factors in hematopoietic stem cells (Solaimani Kartalaei et al., 2015), giving rise to a widespread cellular distribution (Hamann et al., 2015). Hobit comprises DNA-binding zinc finger domains, which closely resemble their homologous domains in Blimp-1 (van Gisbergen et al., 2012; Vieira Braga et al., 2015). In agreement with the presumed role of Hobit as transcription factor, multiple copies of the consensus binding sequence for Blimp-1/Hobit G(T/C)GAAG(T/C) (G/T) (Doody et al., 2007) are identified in the 5′-region of GPR56 (data not shown). In mice, peripheral NK and T cells barely express GPR56 (www.imagen.org), which is in line with the absence of Hobit in these cells (van Gisbergen et al., 2012). Interestingly, resting murine NK cells are minimally cytotoxic; they contain little granzyme B or perforin protein, whereas the respective mRNAs are abundant (Fehniger et al., 2007). Cytokine- and virus-induced activation of murine NK cells results in potent cytotoxicity, associated with a strong increase in granzyme B and perforin protein. It is tempting to speculate that murine NK and T cells do not express GPR56 due to the different ways they acquire cytotoxic capacity.
By studying two pairs of BFPP siblings with the recurrent R565W and C346S mutations in the second extracellular loop and the GAIN domain, respectively (Piao et al., 2005; 2004), which both obstruct cell surface expression of the receptor (Chiang et al., 2011; Jin et al., 2007), we found that GPR56 is not required for the development of functionally competent NK cells. Entirely GPR56-deficient NK cells with the R565W mutation killed K562 cells even more efficiently, indicated by enhanced degranulation, enhanced cytokine secretion, and enhanced induction of apoptosis in target cells. This observation provided a first clue that GPR56 might regulate NK-cell cytotoxicity, a finding that we substantiated in NK-92 cells stably overexpressing GPR56. NK-92–GPR56 cells contained less granzyme B and TNF transcripts at resting state and produced less TNF and IFNγ protein upon PMA stimulation. Moreover, their ability to kill K562 was impaired, as indicated by reduced degranulation, reduced cytokine secretion, and reduced induction of apoptosis in target cells. Similar results were found in more killing-resistant THP1 and HeLa cells, altogether demonstrating that GPR56 inhibits NK-cell cytotoxicity.

Of note, no immune-related clinical phenotype has been reported for BFPP patients. This, however, is not surprising since effector functions of NK cells are balanced by activating and inhibitory signals that are simultaneously delivered to the cells following the engagement of several distinct families of transmembrane receptors (Caliguri, 2008). GPR56 does not belong to a receptor family commonly associated with NK-cell regulation, such as immunoglobulin-like receptors and C-type lectins (Lanier, 2008; Pegram et al., 2011). GPR56 is a member of the aGPCR family. While the functional mechanism of aGPCRs is still poorly understood, evidence accumulates that they are true GPCRs that regulate wide cellular programs through the action of G proteins (Hamann et al., 2015; Monk et al., 2015). Indeed, the broad activity of GPR56 is indicated by its ability to control cytolytic enzymes and pro-inflammatory cytokines, which present the two major arms of NK-cell activity. Moreover, we previously showed that GPR56 inhibits spontaneous and SDF-1-stimulated NK-cell migration (Peng et al., 2011). Studies in other cell types have implicated roles of GPR56 in generation and maintenance of the hematopoietic stem cell pool, cortical development, male fertility, muscle hypertrophy, and melanoma tumor growth and progression (Ackerman et al., 2015; Bae et al., 2014; Chen et al., 2010; Giera et al., 2015; Piao et al., 2004; Saito et al., 2013; Solaimani Kartalaei et al., 2015; White et al., 2014; Xu et al., 2006).

Our data indicate that GPR56 executes its inhibitory activity in concert with the tetraspanin protein CD81. The GPR56–CD81 complex represented one of the first examples of a GPCR in the tetraspanin web, an important membrane protein scaffold for regulating signal transmission (Little et al., 2004). More recently, the Drosophila aGPCR Flamingo was shown to interact in cis with the tetraspanin Van Gogh in the acquisition of planar cell polarity (Lawrence et al., 2008). The tetraspanin web is well known to modulate immune signaling, and CD81 has been shown to inhibit NK-cell functions when cross-linked (Crotta et al., 2002; Tseng and Klimpel, 2002). Our findings that the GPR56–CD81 complex on the NK-cell surface was quickly reduced and relocated to the contact points with the target cells suggested a role in regulating NK-cell activities. Indeed, ligation of GPR56 receptor by mAbs was found to dissociate the GPR56–CD81 complex, leading to enhanced NK-cell cytotoxicity and increased cytokine secretion. Based on these results, we suggest that GPR56 acts
as a cell-autonomous NK-cell inhibitory receptor by laterally crosslinking with CD81. Removing GPR56 hence resulted in stronger NK-cell functions, as exemplified by the GPR56-deficient NK cells of BFPP patients as well as NK-92 and primary NK cells upon activation by PMA, cytokines, and contact with target cells.

At present, it is not known exactly how the GPR56–CD81 complex is recruited to the immune synapses upon NK–target cell conjugation. However, possible mechanisms can be envisioned based on earlier works. We have previously shown that while the majority of the GPR56 NTF–CTF heterodimeric receptor complex is located in the non-raft region, some of the GPR56 CTF is partitioned to the lipid raft microdomains (Chiang et al., 2011). Moreover, although lipid rafts and the tetraspanin-enriched microdomains (TEMs) are considered distinct membrane constitutions, co-clustering of lipid rafts and TEMs is possible upon cell activation or transformation (Krementsov et al., 2010; Ono, 2010).

Signaling molecules, including Gaq/11, Ga12/13, PKCa, RhoA, and mTOR, have been linked to GPR56 in different cell types (Ackerman et al., 2015; Giera et al., 2015; Iguchi et al., 2008; Little et al., 2004; Luo et al., 2011; Paavola et al., 2011; White et al., 2014). Of interest is the specific association with CD81 and Gaq/11, reported by Little et al., in which CD81 was critical in promoting/stabilizing the GPR56–Gaq/11 association (Little et al., 2004). The GPR56–CD81–Gaq/11 complex was dynamically regulated: anti-CD81 mAb led to the uncoupling of Gaq/11 from the GPR56–CD81 complex, while cell activation by PMA dissociated GPR56 from CD81 and Gaq/11, leading to GPR56 internalization. In the present report, we applied a novel, highly selective inhibitor of Gaq/11/14, called FR900359 (Schrage et al., 2015). Of note, FR900359 did not restore cytotoxicity in NK-92–GPR56 cells. Thus, signaling pathways downstream of the GPR56–CD81 complex remain to be elucidated.

The ability to downregulate inhibitory receptors enables effector NK and T cells to unfold their full functional capacity. We found that PMA rapidly and completely downregulates GPR56 through PKC-mediated shedding and internalization. Moreover, an inflammatory milieu, created by the potent NK-cell activating cytokines IL-15 and IL-18 (Fehniger et al., 1999), caused PKC-dependent shedding of GPR56. Receptor shedding is a hallmark of aGPCRs and likely relates to the extended extracellular domains (Hamann et al., 2015). Previous studies indicate that in absence of the NTF, the CTF of GPR56 and other aGPCRs can overtly provide activating signals (Liebscher et al., 2014; Paavola et al., 2011; Paavola and Hall, 2012; Paavola et al., 2014; Stephenson et al., 2013). GPR56 expression on cytotoxic lymphocytes will provide an interesting model to determine the fate and possible activities of an aGPCR upon activation-mediated release of its NTF and to explore therapeutic possibilities provided by the unique structure of this non-canonical GPCR.
Experimental Procedures

Donors and cell isolation
PBMCs were isolated using a Lymphoprep gradient (Axis-Shield, Oslo, Norway) from fresh blood of healthy donors and four BFPP patients, diagnosed with single mutations in GPR56. Studied were two newly identified Dutch siblings of 46 and 49 years (1693C>T, R565W) and 2 previously described Palestinian siblings (1036T>A, C346S) (Piao et al., 2004). Samples were obtained under informed consent and in accordance with ethical guidelines of the Academic Medical Center, Amsterdam, the Netherlands, the Radboudumc, Nijmegen, the Netherlands, and the Schneider Children’s Medical Center, Petah Tiya, Israel. CD56+CD3– NK cells with ≥99% purity were isolated on a FACSaria™ III cell sorter (BD Biosciences, San Diego, CA, USA).

Cell culture and stable transduction
Cells were maintained in the following media supplemented with 10% heat-inactivated fetal bovine serum (FBS): PBMCs, purified CD56+CD3– NK cells, and monocytic THP-1 cells in Roswell Park Memorial Institute (RPMI) 1640 medium; erythroblastic K562 cells and Jurkat T cells in Iscove’s modified Dulbecco’s medium (IMDM); HeLa cells in Dulbecco’s Modified Eagle Medium (DMEM). Human NK-92 cells were cultured in nucleoside-free α-Minimum Essential Medium (α-MEM) containing 12.5% FBS, 12.5% horse serum, 0.2 mM inositol, 0.1 mM 2-mercaptopetethanol, 0.02 mM folic acid, and 100 IU/ml IL-2. Cell culture media and supplements were obtained from Invitrogen (Carlsbad, CA, USA). All cell culture media were supplemented with 2 mM L-glutamine, 10 U/ml penicillin, and 100 μg/ml streptomycin.

Generation of NK-92 cells stably overexpressing GPR56 has been described previously (Peng et al., 2011). The wild type and cleavage deficient mutant (T383A) of GPR56 were transduced using retroviruses in NK-92 cells. For gene knockdown, NK-92 cells were transduced using lentiviruses containing pKLO.1 plasmids with non-target scrambled short hairpin RNA (shRNA) (SHC002; sequence CCGGCAA-CAAGATGAAGAGCACCAACTC) from Sigma-Aldrich (St. Louis, MO, USA) or Eomes shRNA (TRCN000013175; target sequence GCCCACTACAATGTTGTCGA) from Open Biosystems (GE Healthcare, Lafayette, CO, USA). Cells were transduced in retronectin (Takara Bio Inc., Shiga, Japan)-coated plates and selected on 2 ng/ml puromycin (Sigma-Aldrich). NK-92 cells expressing pKLO.1 with Hobit shRNA (TRCN0000162720; CAGAGAGCTCACATCACTT) or Jurkat cells expressing LZRS pBM-IRESEGFP with Hobit fragment were generated previously (Vieira Braga et al., in revision). Transduced Jurkat cells were sorted to ≥95% purity on a FACSaria™ III cell sorter using green fluorescent protein (GFP) expression as selection marker.

Cytotoxicity assay
This assay employs 7-hydroxy-9H-(1,3-dichloro-9,9-dimethylacridin-2-one) (DDAO; Invitrogen) to label target cells and 3,3′-dihexyloxacarbocyanine iodide (DiOC6; Invitrogen) to label live cells. Washed target cells (5x10⁶ cells/ml) were resuspended in 1 mM DDAO/phosphate-buffered saline (PBS), incubated at 37°C for 15 min in the dark, washed, and resuspended in NK-92 medium. PBMCs or NK-92 stable cells were incubated at various effector/target ratios (5/1 to 1/5) with target cells at 37°C for 5 h, followed by addition of 0.1 μg/ml DiOC6 at 37°C for 15 min, and analysis by flow...
cytometry. Alternatively, target cells were labeled with carboxyfluorescein succinimidyl ester (CFSE; Invitrogen) and dead cells with 7-aminoactinomycin D (7-AAD; Invitrogen). Washed target cells (5x10^6 cells/ml) were resuspended in PBS containing CFSE (2 µM for K562, 1 µM for THP-1, and 2.5 µM for HeLa) and incubated at 37°C for 10 min in the dark, followed by quenching the CFSE staining for 5 min on ice. Washed cells were resuspended in NK92 medium. NK-92 stable cells were incubated at various effector/target ratios (40/1 to 1/10) with target cells at 37°C for 4 h, followed by addition 0.5 ml of ice-cold Dulbecco’s PBS (DPBS; Invitrogen), containing 1% bovine serum albumin (BSA) and 5 µg/ml 7-AAD, for 15 min in the dark, and analysis by flow cytometry.

**Cell stimulation**

For activation, 1x10^6 cells/ml PBMCs were incubated for 2 h in medium plus 10 ng/ml PMA (Sigma-Aldrich). For cytokine stimulation, 1x10^6 cells/ml PBMCs were incubated for 12-24 h in medium containing 400 U/ml IL-2, 10 ng/ml IL-15, or 100 ng/ml IL-18 (all R&D Systems, Minneapolis, MN, USA), either alone or in the combination, as indicated. For CD16 Ab cross-linking stimulation, flat 96-well microplates (Corning, Corning, NY, USA) were pre-coated with 10 µg/ml goat anti-mouse immunoglobulin (Ig)G in PBS at 37°C for 2 h. Plates were washed twice with PBS and coated with 10 µg/ml purified anti-CD16 in PBS at 4°C for overnight. Then, plates were washed twice with PBS and blocked with RPMI 1640 medium/10% PBS at 37°C for 1 h. 2x10^6 cells/ml purified CD56+CD3− NK cells were added to the plates. For GPR56 Ab cross linking stimulation 48-well plates (Cellstar, Greiner bio-one) were coated with PBS containing mouse IgG, CG2, CG3, or CG5 at 37°C for 2 h followed by overnight coating at 4°C. After washing the plates with PBS, 2x10^6/ml NK-92-GPR56 cells or primary human NK cells were incubated in coated wells in complete NK-92 medium. Following 2 h of crosslinking at 37°C, 8x10^6/ml K562 cells were added to wells at E/T ratio=2. For NK cytotoxicity assay, K562 cells were labeled with DDAO before adding onto the plates as described above. For cytokine production assay, supernatants were collected following 6 h of stimulation with K562 cells.

Pharmacological inhibitors were added for 1 h at 37°C prior to stimulation. Specific inhibitors of PKC (staurosporine, calphostin, bisindolylmaleimide I), PKB/Akt (Akt1/2 kinase inhibitor), PI3K (LY294002), MAP kinases ((Erk (U0126), JNK (SP600125) and p38 (SB 203580)), MMPs (GM6001), and dynamin (dynasore) were all obtained from Sigma-Aldrich. Inhibitors of ADAM10 and ADAM17 (GW) were generated at the Chemistry Department of Cardiff University; a second ADAM17 inhibitor (TNF484) was kindly provided by Dr. U. Neumann (Novartis, Basel, Switzerland). Ga signaling was inhibited using Y27632 (Sigma-Aldrich), an inhibitor of ROCK downstream of Ga12/13, and FR900359, a selective inhibitor of Gaq/11/14 (Schrage et al., 2015).

**Proliferation assay**

PBMCs were washing three times in PBS, resuspended at 5x10^6 cells/ml in PBS, and labeled with 2.5 µM CFSE by shaking at 37°C for 10 min. Cells were washed three times and subsequently cultured in RPMI 1640 medium with or without 50 U/ml IL-2.
The Adhesion G Protein-Coupled Receptor GPR56/ADGRG1 Is an Inhibitory Receptor on Human NK Cells

for 5 days.

Conjugation assay
Target cells were labeled with CFSE as described above. 1x10^6 of labeled target cells were mixed with 5x10^5 NK-92 cells at an effector/target ratio of 1/2. The cell mixture was centrifuged at 250g for 3 min at 4°C, then placed in a 37°C water bath for the desired lengths of time. After conjugation, cells were gently resuspended, fixed in 2% ice-cold paraformaldehyde/ PBS for 30 min, then subjected to Ab staining using either allophycocyanin (APC)-conjugated anti-CD56 mAb (if K562 and HeLa were used as targets) or APC-conjugated anti-CD2 mAb (if THP-1 was used as a target). Conjugation was analyzed by flow cytometry (FL-1 versus FL-4), and measured by percentage of NK cells that formed conjugates with target cells as calculated by the ratio of two-color events to total effector cell events.

Quantitative PCR
Total RNA was isolated with RNeasy mini kit (Qiagen, Hilden, Germany), and cDNA was synthesized using RevertAid First Strand cDNA Synthesis Kit (Thermo Fisher Scientific, Waltham, MA, USA). Relative gene expression levels were measured using Fast SYBR Green Master Mix (Applied Biosystems, Foster City, CA, USA) on a StepOnePlus™ System (Applied Biosystems) with the cycle threshold method. Expression of specific genes was normalized to human GAPDH (forward 5'-GAACGTCAGCAGGAGTGTGGC-3', reverse 5'-GAAGATGGTAGAGAATTGACAGTTG-3') as endogenous control. The following primers were used: ADGRG1 (forward 5'-GATTGCGCTGGCTTGTGTAG-3', reverse 5'-GACACCAACCGAATTGACAGTTG-3'); B3GAT1 (forward 5'-GAAGCCAGGCCTACT-TCAGCATTG-3', reverse 5'-GTTGAGGTGACAGATGTTG-3'); BCL6 (forward 5'-AACCTGAAAACCCACACTCG-3', reverse 5'-CTGAGATTGGCGCTACT-TCAGCATTG-3'); PDCD1 (forward 5'-CTCAGGGTGACAGAGATTGACAGTTG-3', reverse 5'-GAACGTCAGCAGGAGTGTGGC-3'); PRDM1 (forward 5'-GTGCCCACTGCTCAGGAGAATAACAC-3', reverse 5'-CTCAGGGTGACAGAGATTGACAGTTG-3'); PRF1 (forward 5'-CGCCCTATTCCCTTCTCTTGCTATC-3', reverse 5'-CTCAGGGTGACAGAGATTGACAGTTG-3'); TFN (forward 5'-CTGAGGTGACAGATGTTG-3', reverse 5'-GAACGTCAGCAGGAGTGTGGC-3'); TBR1 (forward 5'-CTCAGGGTGACAGAGATTGACAGTTG-3', reverse 5'-GAACGTCAGCAGGAGTGTGGC-3'); ZNF683 (forward 5'-CATATGGGCAAGAGGTGAGT-3', reverse 5'-GGCAAAGCTTGTGACAGAGATTGACAGTTG-3').

Antibodies and flow cytometry
Conjugated mAbs with the following specificity were used: anti-GPR56 (clone CG4; Biolegend, San Diego, CA, USA); anti-CD2 (clone RPA-2.10; BD Biosciences); anti-CD3 (clone SK7 and UCHT1; BD Biosciences); anti-CD9 (clone ML13; BD Biosciences); anti-CD16 (clone 3G8; BD Biosciences); anti-CD56 (clone NAM16.2; BD Biosciences); anti-CD57 (clone NK-1; BD Biosciences); anti-CD81 (clone 1D6-CD81; eBioscience, San Diego, CA, USA); anti-CD94 (clone HP-3D9; BD Biosciences); anti-CD107a (clone H4A3; eBioscience); anti-CD158a/h (KIR2DL1/S1; clone EB6B;
Chapter 7

Beckman Coulter, Miami, FL, USA); anti-CD158b (KIR2DL2/L3; clone GL183; Beckman Coulter); anti-CD158e (KIR3DL1; clone DX9; BD Biosciences); anti-CD159a (NKG2a; clone #131411; R&D Systems); anti-CD159c (NKG2c; clone #134591; R&D Systems); anti-CD226 (DNAM-1; clone 11A8; Biolegend); anti-CD279 (PD-1; clone EH12.1; BD Biosciences); anti-CD314 (NKG2d; clone 1D11; Biolegend); anti-CD335 (NKP46; clone 9E2; AbD Serotec, Kidlington, UK); anti-CD336 (NKP44; clone P44-8; Biolegend); anti-CD337 (Nkp30; clone P30-15; Biolegend); anti-KLRG1 (kindly provided by Prof. H.P. Pircher, Freiburg (Marcolino et al., 2004)); anti-FcRγ (rabbit polyclonal antibody; Millipore, Bedford, MA, USA); anti-perforin (clone 8G9; BD Biosciences); anti-granzyme B (clone GB11; BD Biosciences); anti-TNF (clone MAb11; eBioscience); anti-IFNγ (clone 4s. B3; eBioscience); anti-T-bet (clone 4B10; Biolegend); anti-Eomes (clone WD1928; eBioscience); anti-PLZF (clone R17-809; BD Biosciences); anti-mouse IgM (clone II/41; eBioscience).

The following purified mAb were used: anti-GPR56 (clone CG2, CG4, CG3, and CG5; Biolegend and (Peng et al., 2011)); anti-CD9 (clone MM2/57; Millipore, Bedford, MA, USA); anti-CD16 (clone 3G8; Biolegend); anti-CD81 (clone TS81 and 5A6; Abcam, Cambridge, UK and Santa Cruz Biotechnology, Dallas, TX, USA); anti-Hobit (Vieira Braga et al., 2015); mouse IgG1 (clone MOPC-21, BD Biosciences).

Staining of extracellular antigens was performed according to standard procedures. For intracellular antigens, cells were first stained for surface markers, followed by fixation with Foxp3 Transcription Factor Staining Buffer Set (eBioscience) and incubation with antibodies directed against intracellular molecules. Flow cytometric analysis was performed on FACSCalibur, FACSCanto II, and LSRFortessa machines (BD Biosciences), and all data were analyzed with FlowJo software (Tree Star, Ashland, OR, USA).

To analyze cell cycle phase distribution, NK-92 cells were washed with cold PBS and fixed in 70% ethanol for 1 h. Fixed cells were stained with 20 μg/ml propidium iodide/0.1% Triton-X (both from Sigma-Aldrich) in the presence of 200 μg/ml RNaseA (Qiagen, Hilden, Germany) for 30 min at room temperature in the dark and analyzed by flow cytometry.

For intracellular cytokine and degranulation staining, PBMCs and stable NK-92 cells were mixed with K562 in the presence of anti-CD107a and incubated at 37°C for 1 h in the dark. A mixture of brefeldin A (1 μg/ml; BD Biosciences) plus monensin (10 μg/ml; BD Biosciences) was then added, and samples were incubated for a further 5 h. Cells were labeled with antibodies recognizing extracellular antigens, fixed/permeabilized, stained for TNF and IFNγ, and examined by flow cytometry.

**Enzyme-linked immunosorbent assay**

Soluble GPR56 was quantified as described (T.-Y. Yang et al., 2015). TNF and IFNγ levels in culture supernatants were assessed using DuoSet ELISA Development Systems from R&D. Spectrophotometric analysis was performed at 450 nm wavelength on a SpectraMax M2 spectrophotometer (Molecular Devices, Sunnyvale, CA, USA) using Softmax Pro 5.3 software (Molecular Devices).

**Indirect immunofluorescence**

NK-92 were conjugated to K562 at 2/1 ratio, centrifuged at 25 μg for 3 min at 4°C, and incubated for 30 min at 37°C. After conjugation, a total of 6×10⁷ cells were

All patients, physicians Dr. D.J.J. Halley (Erasmus MC, Rotterdam), Dr. B. van Bon (Radboudumc, Nijmegen), and M. van Veldhoven (Cello, Rosmalen) for making the investigation possible. We thank Dr. X. Piao

Immunoprecipitation

Cells were lysed in a 1% 3-[3-cholamidopropyl]dimethylammonio]-1-propanesulfonate (CHAPS) buffer containing 20 mM Tris-HCl, pH 7.4, 150 mM NaCl, 5 mM MgCl2, 5% glycerol, and protease inhibitors including 1 mM sodium orthovanadate, 10 µg/ml aprotinin, 5 mM levanosole, 1 mM 4-(2-aminomethyl)benzenesulfonfyl fluoride hydrochloride (AEBSF) and cOmplete protease inhibitor from Roche Diagnostics (Basel, Switzerland). Lysates were extracted on an end-over-end rotator at 4°C for 3 h and collected after removing insoluble fraction by centrifugation at 12,000 rpm for 25 min at 4°C. Supernatants were pre-cleared with Protein G Sepharose (Sigma-Aldrich) for at least 1 hour at 4°C on a rotator, or, for lysates collected from Ab-pre-treated cells, with mouse IgG conjugated to agarose (A0919; Sigma-Aldrich). Specific mAbs (4 µg) were then mixed with pre-cleared lysates (5x10^6 cell equivalents) and incubated on ice for 2 h before adding 20 µl of 1:1 diluted Protein G Sepharose beads. Immunoprecipitates were then collected overnight at 4°C on a rotator, washed five times with cold 1% CHAPS lysis buffer, eluted with 2% Laemmlli buffer at 95°C for 8 min, and resolved on a 8% (for GPR56) or on a 12% (for CD81 and CD9) nonreduced SDS-PAGE. For re-IP, CD81 associated molecules were eluted with 1% Triton X-100 lysis buffer following anti-CD81 (clone TS81) IP. Eluates were then subjected to a second IP using anti-GPR56 (clone CG2) mAb. Immunoprecipitates were analyzed by immunoblotting using anti-GPR56 (clone CG4), anti-CD81 (clone 5A6), and anti-CD9 (clone MM2/57) mAbs.

Statistics

All results are expressed as means ± standard error of the mean (SEM). A Student t-test was used to determine P values. Significance was set at P<0.05.
for helpful suggestions and B. Hooibrink and T.M. van Capel for help with cell sorting. The study was supported by a scholarship from the Ministry of Education, Taiwan, and a fellowship from the European Federation of Immunological Societies (EFIS) to C.C.H. and by grants from the Ministry of Science and Technology, Taiwan (MOST101-2320-B-182-029-MY3 and MOST104-2320-B-182-035-MY3) and the Chang Gung Memorial Hospital (CMRPD1A0181-3, CMRPD1D0072-3, CMRPD1D0391-2) to H.H.L. as well as by the Thyssen Foundation (2015-00387) to K.P.J.M.v.G and J.H. J.H. is a Mercator Fellow of the German Research Foundation (Research Unit 2149).
