ABSTRACT: To realize the potential of near-infrared (NIR) upconversion nanosensitizers for photodynamic therapy of cancer, upconversion luminescence and energy transfer (ET) efficiency from emitter donors to photosensitizer acceptors need to be improved. In the current work, upconversion nanoparticles (UCNPs) with a core/emitter-active shell structure were constructed to enhance not only the upconversion emission but also the ET from the nanoparticles to surface-anchored photosensitizers. The emitter was doped into the shell to bridge the migration of upconverted energy to the surface. NaYF₄:Yb,Er/NaYF₄:Er UCNPs and rose bengal (RB) photosensitizer were employed as an example. The upconversion emission was lifted by up to ~81 times of the core counterpart. The bridge effect of the emitter-doped shell was obvious for the constructed nanophotosensitizer. The emission of the RB photosensitizer was up to ~36 times that of the core counterpart. The NaYF₄:Yb,Er/NaYF₄:Er UCNPs also endow the RB photosensitizers with the most efficient reactive oxygen species production capability under NIR irradiation. In vitro photodynamic tests on glioma cells were conducted to validate the efficacy of the NaYF₄:Yb,Er/NaYF₄:Er/RB agent. Therefore, this work can facilitate the development of ET-based upconversion nanosystems.

KEYWORDS: upconversion nanoparticles, photosensitizer, energy transfer, core/shell, photodynamic therapy

1. INTRODUCTION

Photodynamic therapy (PDT) is a promising therapeutic modality for cancer which threatens human health seriously. PDT can damage localized cancer cells using toxic reactive oxygen species (ROS) generated by light-triggered photosensitizers in the presence of oxygen.¹⁻⁴ Compared with traditional therapeutic methods, including surgery, radiotherapy, and chemotherapy, PDT exhibited advantages of low systemic toxicity, high selectivity, and minimal invasiveness.⁵,⁶ However, the application of PDT has been significantly hindered because photosensitizers are usually triggered by ultraviolet (UV) or visible light, which are susceptible to absorption and scattering and thus have shallow penetration in biological tissues.¹,⁷ Therefore, there is an emerging need to develop near-infrared (NIR) light-excitable photodynamic therapeutic agents.

Rare earth-doped upconversion nanoparticles (UCNPs) are capable of converting NIR excitation light to UV and visible emission light and thus provide a great opportunity.⁸⁻¹⁰ UCNPs are featured in strong photobleaching resistance, deep tissue penetration, and negligible background fluorescence.¹¹,¹² By transferring upconverted excitation energy to the adjacent photosensitizer, UCNPs can serve as NIR light transducers of photodynamic therapeutic agents.¹³⁻¹⁵ To realize the potential of UCNPs for the therapy of deep lesions, the upconversion luminescence and energy transfer (ET) efficiency from emitter donors to surface-anchored photosensitizer acceptors need to be improved. ET efficiency decreases sharply as the donor−acceptor distance increases. Therefore, efforts have been focused mainly on bare-core-structured UCNPs (e.g., NaYF₄:Yb,Er and NaYF₄:Yb,Gd,Tm) to minimize the distance between energy donors (emitter ions in the UCNPs, e.g., Er⁵⁺ and Tm³⁺) and photosensitizer acceptors.¹⁶⁻¹⁸

Shell coating can effectively enhance the luminescence intensity of UCNPs.¹⁹⁻²² Inspired by this, we demonstrated previously theoretically and experimentally that an inert shell with an appropriate thickness can improve ET from the
UCNPs to the surface-bound acceptor.\textsuperscript{23,24} In the past few years, core/shell structured UCNPs, such as LiYF\textsubscript{4}:Er/LiGdF\textsubscript{4}, NaYF\textsubscript{4}:Yb,Er,Gd/NaYF\textsubscript{4}:Gd, NaGdF\textsubscript{4}:Yb,Er,Mn/NaGdF\textsubscript{4}:Yb and NaYF\textsubscript{4}:Yb,Tm/NaYF\textsubscript{4}:Yb/NaNdF\textsubscript{4}:Yb/NaYF\textsubscript{4}, have attracted growing interest for the development of ET systems.\textsuperscript{35–38} The introduction of one or more inert or sensitizer-active shells significantly improves the upconversion luminescence. However, the shell can increase the distance between the inner emitters and the photosensitizing molecules at the surface, thus reducing the ET efficiency. The donor–acceptor distance can be shortened by constructing various unique core/shell structures with the emitter also in the shell, such as NaYF\textsubscript{4}:Yb/NaYF\textsubscript{4}:Yb,Er,\textsuperscript{39} NaLiF\textsubscript{4}:Yb/NaLiF\textsubscript{4}:Yb,Er,\textsuperscript{40} NaYF\textsubscript{4}:Nd,Yb/NaYF\textsubscript{4}:Yb,Er,\textsuperscript{41} NaYF\textsubscript{4}:Yb,Er,\textsuperscript{42} NaYF\textsubscript{4}:Er/NaYF\textsubscript{4}:Er,\textsuperscript{43} and NaYF\textsubscript{4}:Nd,Yb/NaYF\textsubscript{4}:Yb/NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}.\textsuperscript{44} Despite these advances, the outermost shell can directly expose the emitter to the external environment or separate the emitter from the surface acceptor, thus reducing the upconversion luminescence and/or the ET efficiency. Therefore, a sweet spot between upconversion luminescence and ET efficiency needs to be identified to promote the practical applications of NIR upconversion nanosensors in PDT.

In this work, new NIR light excitable PDT nanoagents were constructed using NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}:Er as the core/emitter-active-shell structured UCNPs and rose bengal (RB) as the photosensitizer. NaYF\textsubscript{4} shell was applied to enhance the upconversion luminescence by surface passivation, and Er\textsuperscript{3+} was introduced into the shell to bridge ET from the Er\textsuperscript{3+} emitter in the core to the surface-anchored RB acceptor. The concentration of Er\textsuperscript{3+} in the shell and the shell thickness were optimized to achieve the best RB efficacy. The developed NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}:Er UCNPs exhibited the strongest RB emission and produced the highest amount of ROS under 980 nm excitation, compared with control groups of different structures and doping patterns. In vitro photodynamic killing of glioma cells was carried out as a proof of principle.

2. EXPERIMENTAL SECTION

2.1. Reagents and Instrumentation. Details of the reagents and instruments used for material characterization are provided in the Supporting Information.

2.2. Synthesis of NaYF\textsubscript{4}:Yb, Er/NaYF\textsubscript{4}: Er Nanoparticles. Olate-capped NaYF\textsubscript{4}, 20% Yb, 2% Er/NaYF\textsubscript{4}, x% Er (x = 0–5.0) UCNPs were prepared by the co-precipitation method using AOT as the surfactant and the reaction medium (water/oil emulsion). To prepare a core/shell-structured UCNPs, NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}:Er UCNPs were prepared by following the same method as that for NaYF\textsubscript{4}:Yb,Er core nanocrystals. The concentration of Er\textsuperscript{3+} in the shell and the shell thickness were optimized to achieve the best RB efficacy. The developed NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}:Er UCNPs exhibited the strongest RB emission and produced the highest amount of ROS under 980 nm excitation, compared with control groups of different structures and doping patterns. In vitro photodynamic killing of glioma cells was carried out as a proof of principle.

2.3. Preparation of UCNP/RB Therapeutic Agents. UCNPs (1 mL, ~10 mg/mL) were mixed with HCl (0.05 M), and the mixture was stirred for 24 h to remove the oleate ligand. After they were washed with isopropanol and dispersed in water, 50 μL of poly(allylamine) (PAAM) was added, and the mixture was stirred for 20 h to further modify UCNPs with amino groups. To incorporate the RB photosensitizer to the UCNPs covalently, 10 μg/mL of carboxyl-modified RB (RB-HA)\textsuperscript{45} was first reacted with N-(3-dimethylaminopropyl)-N’-ethylcarbodiimide hydrochloride (EDC, 100 μg/mL) and N-hydroxysulfosuccinimide sodium salt (NHS, 100 μg/mL) for 2 h. Then, 0.5 mL of UCNP/PAAM (~0.14 nmol/mL, estimated according to the size and density of hexagonal NaYF\textsubscript{4}) was added and reacted for a further 24 h. The resulting UCNP/RB was washed several times using dimethylsulfoxide (DMSO) and stored in DMSO.

2.4. Detection of ROS. A dimethyl formamide solution was prepared by mixing 1,3-diphenylisobenzofuran (DPBF, 20 μL, 10 mM) with 1 mL of RB, ~22 nm NaYF\textsubscript{4}:Yb,Er/PAAM, ~42 nm NaYF\textsubscript{4}:Yb,Er/PAAM, ~42 nm NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}:PAAM, ~42 nm NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}:Er/PAAM, and the conjugates of the above UCNPs with RB, respectively. The concentrations of UCNP/PAAM and UCNP/RB were all ~0.14 nmol/mL. The mixtures were then irradiated with a 980 nm laser (0.7 W/cm\textsuperscript{2}) in the dark. The absorbance at 417 nm was recorded every 5 min.

2.5. Cytotoxicity of UCNP/RB Therapeutic Agents. Glioma cells (U87MG cell line) were used to study the cytotoxicity of the conjugates of RB and the four types of UCNPs, which were ~22 nm NaYF\textsubscript{4}:Yb,Er, ~42 nm NaYF\textsubscript{4}:Yb,Er/PAAM, ~42 nm NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}/PAAM, ~42 nm NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}:Er/PAAM, and ~42 nm NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}. 0.5% Er/PAAM, and the conjugates of the above UCNPs with RB, respectively. The radiation YCl\textsubscript{3}/YbCl\textsubscript{3}/ErCl\textsubscript{3} (0.78 mmol/0.20 mmol/0.02 mmol) in deionized water and dispersed in cyclohexane. The samples were washed with ethanol/acetone three times and dispersed in cyclohexane.

2.6. Intracellular ROS Production by UCNP/RB Therapeutic Agents. U87MG cells were seeded into 96-well plates (10\textsuperscript{4} cells/well), incubated for 24 h. Subsequently, 100 μL of UCNP/RB therapeutic agents dispersed in DMEM at various concentrations were added into the wells and incubated for 24 h. After adding the cell counting kit-8 (CCK-8, 10 μL) reagent and culturing for another 2 h, the absorbance at 450 nm was recorded with a microplate spectrophotometer (WELLCSCAN MK3, Labsystems Dragon, America) to calculate cell viability.

Flow cytometric analysis was also performed to evaluate the cytotoxicity of the UCNP/RB therapeutic agents toward U87MG cells. DMEM was removed after U87MG cells were seeded into six-well plates and incubated for 24 h. Then, 500 μg/mL of UCNP/RB therapeutic agents (including ~22 nm NaYF\textsubscript{4}:Yb,Er/RB, ~42 nm NaYF\textsubscript{4}:Yb,Er/RB, ~42 nm NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}, and ~42 nm NaYF\textsubscript{4}:Yb,Er/NaYF\textsubscript{4}:Er/RB) dispersed in DMEM were added into the wells. After incubation for 24 h, U87MG cells were harvested with trypsin (0.05%) and washed twice using phosphate-buffered saline (PBS). Afterward, 1 x 10\textsuperscript{5} cells in binding PBS (100 μL) containing calcein sodium (10%) were added to a centrifuge tube (1.5 mL) and incubated with Annexin-V-fluorescein isothiocyanate (5 μL/L) and propidium iodide (PI, 5 μL/L) for 20 min in the dark. After it was washed twice with PBS, the cell suspension was used for flow cytometric analysis (BD FACSCalibur, America).
(500 μg/mL), respectively. After the cells were cultured for another 4 h in the new media, groups 2−7 and 12−15 were exposed to a 980 nm laser (0.7 W/cm²) for 10 min. 2′,7′-Dichlorodihydrofluorescein diacetate (DCFH-DA, 10 μL) reagent was then added to each well and incubated for 20 min. After being washed with PBS three times, the cells were imaged using a fluorescence microscope.

2.7. Photodynamic Killing of Cancer Cells with UCNP/RB Therapeutic Agents. The viability of U87MG cells in the aforementioned 15 groups described in Section 2.6 was first used to indicate the photodynamic therapeutic efficacy of UCNP/RB therapeutic agents. After NIR treatment (0.7 W/cm²) for 10 min, a CCK-8 reagent (10 μL), instead of DCFH-DA, was added to the wells and incubated for 2 h. The absorbance at 450 nm was recorded to calculate cell viability. U87MG cells treated with conditions described in Section 2.6 were then observed with a fluorescent microscope after they were stained with calcein-AM/PI solutions for 20 min and washed with PBS three times.

2.8. Statistical Analysis. Student’s t-test was used to evaluate statistical significance. *p < 0.05, **p < 0.01, and ***p < 0.001 were considered statistically significant. Data are shown as mean ± standard deviation (n = 3).

3. RESULTS AND DISCUSSION

3.1. Construction of UCNP/RB Therapeutic Agents. The synthesis procedures of the core/emitter-active shell UCNP/RB therapeutic agents are presented in Figure 1a. Typical 20% Yb³⁺, 2% Er³⁺ codoped NaYF₄ UCNPs were first synthesized as the core in solvents with high boiling points (OA/ODE).⁴²,⁴³ Er³⁺-doped NaYF₄ was then coated by Ostwald ripening according to a reported procedure.⁴⁰ To anchor the RB photosensitizer on UCNPs, as-prepared UCNPs were treated with HCl to remove the oleate ligand and further modified with amino-abundant PAAM. Finally, the amino-modified UCNPs were incorporated with carboxyl-
modified RB through EDC/NHS crosslinking. The UCNP can transfer upconverted excitation energy to surface-bound RB molecules, which then produce cytotoxic ROS.

The transmission electron microscope (TEM) images of NaYF₄:Yb,Er core structured UCNP and NaYF₄:Yb,Er/NaYF₄:Er core/shell structured UCNP with various concentrations of Er³⁺ in the shell are shown in Figure 1b–h. All the samples were quasi-spherical in shape. The core UCNP were approximately 22 nm in diameter, and the core/shell UCNP with various Er³⁺ doping concentrations were all approximately 32 nm in diameter. Thus, the shell thickness was ~5 nm. Dynamic light scattering (DLS) results indicated a narrow size distribution of as-prepared UCNP (Figure S1). The actual doping concentrations of Yb³⁺ and Er³⁺ in NaYF₄:Yb,Er core were determined to be 19.0 and 2.1%, respectively, using inductively coupled plasma analysis, and an increasing amount of Er³⁺ was also confirmed from the NaYF₄:Yb,Er/NaYF₄:Er samples with an increasing concentration of Er³⁺ in the shell (Table S1). X-ray diffraction (XRD) patterns (Figure 1i) indicated that these UCNP were in the hexagonal phase, a more effective crystal phase than its cubic counterpart for enhanced upconversion efficiency.⁴⁴,⁴⁵

Upconversion luminescence of the UCNP was investigated under 980 nm excitation. As shown in Figure 2, two green emission peaks centered at 520 and 540 nm and one red emission peak centered at 655 nm appeared. They were ascribed to ⁴S⁷/₂⁻→⁴I₁₅/₂, ⁴S⁵/₂⁻→⁴I₇/₂, and ⁴S⁹/₂⁻→⁴I₁₅/₂ transitions in Er³⁺, respectively. The upconversion luminescence of NaYF₄:Yb,Er was enhanced by one order of magnitude after it was coated by an inert shell of NaYF₄. It resulted from efficient surface passivation of Er³⁺ emitters from surface defects, ligand, solvent, and so on.⁴⁶,⁴⁷ As the concentration of the Er³⁺ emitters doped in the NaYF₄ shell gradually increased to 0.5%, the upconversion luminescence intensity further increased. It indicated that Er³⁺ in the shell can also act as a normal emitter to produce upconversion luminescence. However, when Er³⁺ concentration in the shell continued to increase, the luminescence intensity declined. It implied that the upconverted excitation energy can dissipate to the surface via Er³⁺ in the shell. That is, the surface passivation effect of the shell was suppressed. Thus, it is essential to control the concentration of Er³⁺ doped in the shell to enhance not only the upconversion emission but also the ET to surface-anchored entities.

The coupling process of core/emitter-active-shell UCNP with the RB photosensitizers was verified using Fourier-transform infrared (FTIR) spectroscopy (Figure 3). There were four main absorption peaks corresponding to oleate-capped UCNP. They were centered at around 2930, 2850, 1570, and 1470 cm⁻¹, which originated from stretching vibrations of –CH₂ and –CH₃ and asymmetric and symmetric stretching vibrations of carboxylate anions, respectively. These absorption peaks disappeared after the oleate ligand was removed. Successful PAAM modification was verified by the appearance of two absorption peaks originating from the bending vibration of N–H (1580 cm⁻¹) and stretching vibration of C–N (1113 cm⁻¹). The resulting size increase (~7 nm) relative to the bare UCNP was also observed in the DLS measurements (Figure S2). Two absorption peaks resulting from the stretching vibration of C=O (1725 cm⁻¹) and deformation vibration of –OH (950 cm⁻¹) in the carboxyl groups were observed from RB-HA. After it was conjugated with the UCNP, the two absorption peaks disappeared, and an additional absorption peak was observed at 1634 cm⁻¹. The new peak originated from the stretching vibration of C=O in the amide group, indicating that covalent interactions existed between UCNP and the RB photosensitizer. The centrifugal supernatant was analyzed, and the number of RB photosensitizers coupled onto the surface of each NaYF₄:Yb,Er/NaYF₄:Er core/shell structured UCNP with various concentrations of Er³⁺ in the shell was estimated to be approximately 290 ± 18. Thus, similar amounts of RB can be incorporated into the system under the same conditions.

The upconversion luminescence spectra of the UCNP/RB therapeutic agents with various doping concentrations of Er³⁺...
in the shell are presented in Figure 4a. There were three emission peaks from Er$^{3+}$ ions and a new emission peak centered at 590 nm, which originated from surface-anchored RB excited by the energy transferred from the UCNPs. The integrated emission intensities of RB anchored on the core/shell structured UCNPs relative to that on the core structured UCNPs are presented in Figure 4b. Compared with the core structured UCNPs, a proper shell coating improved the

Figure 5. (a) Emission spectra of NaYF$_4$:Yb,Er/NaYF$_4$:Er/RB therapeutic agents with various shell thicknesses under 980 nm excitation. (b) RB emission intensities integrated in the range of 565−630 nm from (a).

Figure 6. Emission spectra of (a) ∼22 nm NaYF$_4$:Yb,Er/PAAM, (b) ∼42 nm NaYF$_4$:Yb,Er/PAAM, (c) ∼42 nm NaYF$_4$:Yb,Er/NaYF$_4$/PAAM, and (d) ∼42 nm NaYF$_4$:Yb,Er/NaYF$_4$:0.5% Er/PAAM with and without RB attached under 980 nm excitation. (e) Emission intensities of the UCNPs integrated in the range of 515−565 nm, and RB emission intensities integrated in the range of 565−630 nm from (a−d). (f) ET efficiency of UCNP/RB therapeutic agents calculated from (a−d) with the intensity of red emission as an internal reference.
The intensity of RB emission by one order of magnitude. The maximum RB emission intensity was achieved when 0.5% Er3+ ions were doped in the NaYF4 shell. It was attributed to the ET-bridging effect of the Er3+ ions. ET efficiency ($\eta$) was calculated using $\eta = 1 - I_{DA}/I_D$, where $I_{DA}$ and $I_D$ are green emission intensities of UCNP/RB and UCNP/PAAM, respectively.\textsuperscript{48} The ET efficiency from the core structured UCNPs to RB was the highest when the distance between the Er$^{3+}$ emitters and RB was the shortest (Figure 4b). When a NaYF$_4$ shell with a thickness of $\sim$5 nm was coated over the core, ET efficiency decreased markedly. It is because the Er$^{3+}$ emitters in the core were far from the RB acceptors. When moderate amounts of Er$^{3+}$ ions were introduced into the shell, the upconverted excitation energy from Er$^{3+}$ ions in the core was able to migrate to the surface of the nanoparticles and further transfer to the RB photosensitizer. Thus, the ET efficiency increased distinctly. The slight decline in ET efficiency at high Er$^{3+}$ concentrations can be ascribed to the reduced upconversion emission (Figure 2b) that shortens the ET interaction distance.\textsuperscript{35,48} The results demonstrate that the core/emitter-active-shell structured UCNPs can enhance acceptor efficacy.

Thickness of the shell containing 0.5% Er$^{3+}$ emitters was then adjusted to achieve the optimum RB efficacy. TEM images of the UCNPs with different shell thicknesses are presented in Figure S3. The average sizes of UCNPs from CS1 to CS8 were approximately 23, 27, 32, 34, 37, 45, and 55 nm, respectively. The corresponding shell thickness was approximately 0.5, 2.5, 5, 6, 7.5, 10, 11.5, and 16.5 nm, respectively. As shell thickness increased, the upconversion luminescence intensity increased monotonically due to enhanced surface passivation (Figure S4). The upconversion luminescence spectra of the corresponding UCNP/RB therapeutic agents with various shell thicknesses are presented in Figure 5a, and the integrated RB emission intensities are shown in Figure 5b. The strongest RB emission occurred when the shell thickness was 10 nm ($\sim$42 nm in diameter). The RB emission was approximately 36 times that of the core counterpart. Therefore, the shell thickness can be optimized by balancing enhanced upconversion emission (Figure S4) and decreased ET efficiency (Figure S5). The remarkable enhancement of RB emission resulted from the synergistic effect of shell surface passivation and ET bridging by Er$^{3+}$ ions.

Fluorescence images of U87MG cells stained by calcein-AM (green, live cells) and PI (red, dead cells): (a) blank; (b) NIR irradiation; (c) RB; (d) $\sim$22 nm NaYF$_4$:Yb,Er/PAAM, (e) $\sim$42 nm NaYF$_4$:Yb,Er/PAAM, (f) $\sim$42 nm NaYF$_4$:Yb,Er/NaYF$_4$/PAAM, and (g) $\sim$42 nm NaYF$_4$:Yb,Er/NaYF$_4$/Er/PAAM under NIR irradiation; (h) $\sim$22 nm NaYF$_4$:Yb,Er/RB, (i) $\sim$42 nm NaYF$_4$:Yb,Er/RB, (j) $\sim$42 nm NaYF$_4$:Yb,Er/NaYF$_4$/RB, and (k) $\sim$42 nm NaYF$_4$:Yb,Er/NaYF$_4$/Er/RB without NIR irradiation; (l) $\sim$22 nm NaYF$_4$:Yb,Er/RB, (m) $\sim$42 nm NaYF$_4$:Yb,Er/RB, (n) $\sim$42 nm NaYF$_4$:Yb,Er/NaYF$_4$/RB, and (o) $\sim$42 nm NaYF$_4$:Yb,Er/NaYF$_4$/Er/RB under NIR irradiation. NIR irradiation has a power density of 0.70 W/cm$^2$ and an exposure time of 10 min.
3.2. Comparison of the RB Efficacy Excited by UCNPs with Different Structures. To further demonstrate the superiority of core/emitter-active-shell structure in improving acceptor efficacy, the intensity of the RB emission excited by the ~42 nm NaYF₄:Yb,Er/NaYF₄:0.5% Er core/shell structured UCNPs was compared with that excited by other typically used UCNPs structures (Figure 6a–d). In addition to the ~22 nm NaYF₄:Yb,Er core used to construct core/emitter-active-shell structured UCNPs, NaYF₄:Yb,Er core and NaYF₄:Yb,Er/NaYF₄ core/inert-shell structured UCNPs with the same size (~42 nm) as the core/emitter-active-shell structured UCNPs were also used. Although the upconversion luminescence of the ~42 nm NaYF₄:Yb,Er core was approximately 14 times that of its ~22 nm counterpart, it was still much lower than that of the NaYF₄:Yb,Er/NaYF₄:0.5% Er core/shell structured UCNPs (Figure 6e). The enhanced upconversion luminescence and ET-bridging effect of Er³⁺ in the shell endowed NaYF₄:Yb,Er/NaYF₄:0.5% Er with similar ET efficiency to the same-sized NaYF₄:Yb,Er core (Figure 6f). As a result, the RB emission intensity of NaYF₄:Yb,Er/NaYF₄:0.5% Er/RB was much stronger than NaYF₄:Yb,Er RB (Figure 6e). When a 10 nm NaYF₄ inert shell was coated on the ~22 nm NaYF₄:Yb,Er UCNPs, the ET efficiency decreased markedly because the distance between the Er³⁺ emitters and the RB acceptors increased (Figure 6f).

However, the RB emission intensity increased by approximately 13 times owing to the enhanced upconversion luminescence (Figure 6e). When 0.5% Er³⁺ was doped into the shell to bridge the ET between the Er³⁺ emitter and RB acceptor, the ET efficiency increased (Figure 6f). Simultaneously, the upconversion luminescence intensity further improved by 3.1 times (Figure 6e). Thus, the strongest RB emission was achieved with the NaYF₄:Yb,Er/NaYF₄:0.5% Er core/shell structured UCNPs. It is worth noting that the ET efficiency calculated according to the quenched upconversion luminescence (Figure 6f) includes both radiative (reabsorption) and nonradiative ( Förster resonance ET, i.e., FRET) pathways. The decay lifetimes of upconversion emission were further used to calculate the FRET efficiency by using \( \eta_{\text{FRET}} = 1 - \frac{\tau_{\text{DA}}}{\tau_{\text{D}}} \), where \( \tau_{\text{DA}} \) and \( \tau_{\text{D}} \) are decay lifetimes of the green emission from UCNPs/RB and UCNPs/PAAM, respectively. Variation of FRET efficiency (Figure 5e) was similar to that of total ET efficiency (Figure 6f). The significantly increased FRET efficiency of NaYF₄:Yb,Er/NaYF₄:Er/RB relative to NaYF₄:Yb,Er/NaYF₄:RB further demonstrates the ET-bridging effect of Er³⁺ doped in the shell.

The capability of the UCNPs/RB therapeutic agents with various structures for producing ROS was then investigated using DPBF. The absorbance of DPBF at 417 nm decreases when it is oxidized by the produced ROS,⁴⁹ and therefore, this decrease in absorbance can be correlated to the amount of ROS produced. Figure 7 shows that the ROS was not generated when exposing RB or the UCNPs to the NIR light with a power density of 0.7 W/cm², which is below the safety threshold of a 980 nm laser.⁵⁰ When UCNPs/RB therapeutic agents were irradiated using the 980 nm laser, ROS was produced. Variation trend of the amount of ROS was consistent with that of the RB emission intensity in Figure 6e. The NaYF₄:Yb,Er/NaYF₄:0.5% Er core/shell UCNPs/RB therapeutic agent produced the highest amount of ROS. Therefore, the core/emitter-active-shell structured UCNPs are more efficient than both core and core/inert-shell structured UCNPs in transferring energy to the RB acceptor.

3.3. Photodynamic Killing of Cancer Cells with UCNPs/ RB Therapeutic Agents. The intracellular ROS production and photodynamic performance of the UCNPs/RB therapeutic agents were investigated using human glioblastoma cells (U87MG cell line). The stability of the UCNPs/RB therapeutic agents was firstly evaluated. No noticeable precipitation occurred after UCNPs/RB therapeutic agents were dispersed in water, PBS, and DMEM for one week (Figure S7). It indicated good stability of UCNPs/RB therapeutic agents. Cytotoxicity of UCNPs/RB therapeutic agents with four different UCNPs structures was then evaluated using the CCK-8 method (Figure S8) and flow cytometry analysis (Figure S9). Both the methods showed cell viabilities of over 95% when the concentration of the UCNPs/RB therapeutic agents reached 500 µg/mL, indicating their negligible cytotoxicity to U87MG cells at this concentration. Therefore, 500 µg/mL was used as the concentration of the UCNPs/RB therapeutic agents in the following cell experiments. ROS production in the U87MG cells was observed with DCFH-DA, which reacted with ROS in the cells to produce green fluorescence under excitation.⁵¹,⁵² Figure S10 shows fluorescence images of the cells under different treatments. The amount of ROS determined from the brightness of the green fluorescence agreed with that determined from the DPBF experiments (Figure 7). The core/emitter-active shell UCNPs/RB therapeutic agent produced the most ROS for killing cancer cells.

The cell-killing effect of ROS produced by UCNPs/RB therapeutic agents was then studied. It can be seen from Figure 8 that only the cells treated with both UCNPs/RB therapeutic agents and NIR irradiation were killed efficiently, and more than 95% of the cells treated with RB or UCNPs and NIR irradiation remained alive. The cell mortality rate correlated with the amount of ROS produced by the UCNPs/RB therapeutic agents with different structures. For the UCNPs/RB therapeutic agents, the core/inert-shell UCNPs structure killed cells more efficiently than the commonly used core UCNPs structure, and the newly developed core/emitter-active shell UCNPs structure further improved the cell mortality rate to 90%.

The photodynamic killing of gliona cells by the UCNPs/RB therapeutic agents was further visualized using calcein-AM/PI staining (Figure 9). Green: live cells; red: dead cells). No dead cells appeared when the cells were treated with NIR irradiation only, NIR irradiation with RB or UCNPs, and UCNPs/RB therapeutic agents only. However, dead cells were observed when the UCNPs/RB therapeutic agents were used in combination with NIR exposure. The amount of dead cells correlated with the cell mortality rate under the same conditions (Figure 8). The UCNPs/RB therapeutic agents with the core/emitter-active shell structure killed the most cancer cells under NIR irradiation.

4. CONCLUSIONS

In summary, an efficient NIR light-excitable photodynamic therapeutic agent was developed using NaYF₄:Yb,Er/NaYF₄:Er core/shell UCNPs and an RB photosensitizer. The core/shell UCNPs/RB therapeutic agent with 0.5% Er³⁺ doped in a 10 nm shell exhibited the strongest RB emission, which was ~36 times that of the core counterpart. This strong RB emission originated from surface passivation-induced upconversion luminescence enhancement and Er³⁺-bridged efficient ET from the core of the UCNPs to the surface-bound RB
acceptor. Compared with the commonly used core and core/inert shell-structured UCNPs, the core/emitter-active shell structured UCNPs also endowed the RB photosensitizer with the most efficient ROS production capability under NIR irradiation. It was further demonstrated by photodynamic killing of glioma cells using UCNP/RB therapeutic agents. The results presented herein can facilitate the design of UCNP-based ET systems for broad applications in phototherapies, biosensing, optical storage, and so on.
