Randomised controlled trial comparing two different intravenous immunoglobulins in chronic inflammatory demyelinating polyradiculoneuropathy

ABSTRACT

Background Different preparations of intravenous immunoglobulin (IVIg) are considered to have comparable clinical efficacy but this has never been formally investigated. Some patients with chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) report that some IVIg brands are more effective than others. A liquid IVIg preparation is more user friendly and potentially can be infused at a faster rate.

Objectives The primary objective was to compare the efficacy of two different IVIg brands in CIDP. The secondary objective was to compare their safety.

Methods This was an investigator-initiated multi-centre randomised controlled double-blind trial. Twenty-seven patients with active but stable CIDP treated with their individual stable IVIg (Gammagard S/D) maintenance dose and interval were randomised to receive four infusions of freeze-dried 5% IVIg (Gammagard S/D) or the new liquid 10% IVIg (Kiovig). The overall disability sum score (ODSS) was used as the primary outcome scale. The equivalence margin was defined as a difference of $1 point in mean ODSS between treatment groups. Main secondary outcome scales were the MRC sum score and the Vigorimeter.

Results Repeated measurements analysis of variance, adjusted for baseline ODSS, showed a clinically insignificant treatment difference of 0.004 (95% CI –0.4 to 0.4). We also found no significant differences in any of the other outcome measures. Besides a lower occurrence of cold shivers in patients randomised to Kiovig (p=0.03), no significant differences were found in the occurrence of adverse events.

Conclusions This trial demonstrated equal clinical efficacy between a freeze-dried and a liquid IVIg preparation for maintenance treatment of CIDP.

INTRODUCTION

Clinical trials have proven the efficacy of intravenous immunoglobulin (IVIg) for the treatment of chronic inflammatory demyelinating polyradiculoneuropathy (CIDP). The efficacy of intermittent IVIg in CIDP has been shown to last for a period of at least 24 weeks. However, most patients need IVIg treatment for several years. In many CIDP patients, various brands of IVIg are used over the years, often depending on what is available in the hospital pharmacy. Although some authors recommend that switching between IVIg brands should only occur under careful professional supervision, in practice this is usually done without any specific safety measures. IVIg is increasingly being used for various neurological conditions. Various IVIg brands are generally assumed to be equivalent, but some patients report some brands as more efficacious than others. When CIDP patients show no favourable response to IVIg it is not known whether treatment with an alternative brand might be beneficial. IVIg brands differ in their composition and production processes, which may affect their efficacy and tolerability.

Whether this reflects differences in efficacy or safety in immune-mediated neuropathies has never been investigated and, therefore, trials comparing different preparations are recommended. The freeze-dried lyophilised brand Gammagard S/D has been used in randomised controlled trials in autoimmune polyneuropathies. The manufacturing process of the new liquid IVIg preparation Kiovig employs a Cohn-Oncley cold alcohol fractionation procedure to isolate the IgG fraction, which is further purified using chromatography to yield a solution containing $98% IgG instead of $90% IgG in Gammagard S/D. Kiovig contains a different distribution of IgG subclasses and no added glucose, sodium or preservatives. It is more concentrated and can be infused at a faster rate with a reduced volume load.

We compared the efficacy and safety of these two products in a controlled double-blind trial. A group of active but stable CIDP patients treated with a stable maintenance dosage of the 5% freeze-dried IVIg preparation were randomised to the same product or to an equivalent dosage of a more concentrated 10% liquid IVIg preparation.

METHODS

This investigator-initiated trial was conducted at three university-affiliated neuromuscular disease centres in the Netherlands and was approved by the Medical Ethical Committees of these centres and the competent authority. This study was conducted in compliance with the E6 International Conference on Harmonization guideline for Good Clinical Practice and following local regulations. Monitoring was conducted by an Association of Clinical Research Professionals (ACRP) accredited monitor. A data monitoring committee regularly assessed the progress of the trial and the safety data. Written informed consent was obtained from all patients. This CIC trial (comparing IVIg in...
CIDP) is registered in the International Standard Randomised Controlled Trial number register as ISRCTN52121370.

Subjects
Inclusion criteria were:
1. Diagnosis of CIDP made by a consultant neurologist and fulfilling the American Academy of Neurology clinical research criteria.17
2. Age ≥18 y.
3. Initial chronically progressive, stepwise progressive or recurrent weakness of all extremities, developing over at least 2 months, with reduced or absent tendon reflexes.
4. Observed and documented clear improvement of muscle function after the first use of Gammagard S/D.
5. Active CIDP defined by an overall disability sum score (ODSS)18 grade ≥2 and a Medical Research Council (MRC) grade ≤4 in at least one of the muscles assessed in the MRC sum score19 before start of the trial or following a reduction of IVIg dose at some time within the last 12 months before start of the trial.
6. Ongoing intermittent treatment with IVIg (Gammagard S/D) leading to a stable condition. The individual dose must have been stable (within a 25% range of the total dose) for at least 8 weeks and unchanged within the last 4 weeks before start of the trial.
7. Electromyography findings compatible with CIDP at least once during their illness.20,21
8. Fatigue severity scale (FSS24), Short Form (36) Health Survey, Dutch language acute version 1 (SF-3625) and the Rotterdam handicap scale (RHS26).

Exclusion criteria were:
1. Known hereditary neuropathy or severe concomitant diseases such as HIV infection, Lyme disease, chronic active hepatitis, congestive heart failure, systemic lupus erythematosus, drug or toxin induced neuropathy, vasculitis and malignancies.
2. IgM paraprotein with anti-myelin-associated glycoprotein (MAG) antibodies.
3. Multifocal motor neuropathy (MMN), fulfilling the European Federation of Neurological Societies/Peripheral Nerve Society criteria.22
4. Atypical CIDP with pure sensory or persistent unifocal impairment or significant central nervous system involvement.
5. Treatment with another IVIg brand than Gammagard S/D during the previous 8 weeks.
6. Participation in a controlled trial of a medicinal product or toxin induced neuropathy, vasculitis and malignancies.
7. Participation in a study that may interfere with the efficacy or safety evaluation of the study drug.
8. Known hereditary neuropathy or severe concomitant diseases such as HIV infection, Lyme disease, chronic active hepatitis, congestive heart failure, systemic lupus erythematosus, drug or toxin induced neuropathy, vasculitis and malignancies.
9. Known hereditary neuropathy or severe concomitant diseases such as HIV infection, Lyme disease, chronic active hepatitis, congestive heart failure, systemic lupus erythematosus, drug or toxin induced neuropathy, vasculitis and malignancies.

Study design
The trial consisted of 10 infusions in three phases. First, an open label phase with one Gammagard S/D infusion, second a double-blind phase with four blinded infusions and third an open-label phase with five Kiovig infusions (figure 1). Patients were treated in the hospital daycare centre or at home according to where they were treated prior to trial entry. Immediately before infusions 1 and 2 (baseline), 4 and 6 (blind phase), and 8 and 10 (open-label phase), a neurological examination, including the MRC sum score (6 muscles) and INCAT sensory sum score (ISS), was carried out by the assessor (KK). After every infusion, the ODSS as well as the muscle grip strength (vigorimeter) were recorded (figure 1). During every infusion and 1 week thereafter the patient was asked to record adverse events (AEs). One week after each infusion the patient completed the following questionnaires: Fatigue severity scale (FSS24), Short Form (36) Health Survey, Dutch language acute version 1 (SF-3625) and the Rotterdam handicap scale (RHS26).

Study drug
Patients were randomised to receive four infusions of 5% (50 g/l) freeze-dried IVIg (Gammagard S/D, Baxter AG, Vienna, Austria) or the new 10% (100 g/l) liquid IVIg (Kiovig, Baxter AG, Vienna, Austria). All included patients had been treated successfully with maintenance IVIg before start of the trial (mean 5 y; range 5 months to 13 y). For both brands, the IVIg dosage and frequency for each patient was kept the same as their treatment regimen prior to trial entry and remained constant throughout the whole trial. One central trial pharmacist was responsible for the reconstitution (if necessary), packaging, labelling and distribution of the trial medication during the double-blind phase.

Randomisation and blinding
We used a computer-generated randomisation list produced by a statistician (WH). A block randomisation was made for each centre. Patients were checked for eligibility and enrolled by the principal investigator (PD) in agreement with the main investigators of the three centres. The assessor allocated the next available number on entry after consent was given. Allocation concealment was ensured via sequentially numbered, opaque, sealed envelopes distributed by the statistician to the principal investigator. After randomisation, the prescription was faxed by the principal investigator to the pharmacy. Patients, the assessor (KK) and the blinded neurologist who assessed the AEs were all blind to the drug allocations. We did not dilute the 10% (Kiovig) solution to a 5% solution as we had no data regarding its stability. Due to the different volumes of the preparations, the nurses who were experienced in administering the IVIg could not be blind for the drug assignment as they had to adjust the

Key
- ODSS and Vigorimeter (just prior to infusion)
- MRC Sum Score, ISS (just prior to infusion)
- Gammagard S/D Infusion
- Gammagard S/D or Kiovig infusions
- Kiovig infusions
- Side-effects questionnaire (during and one week after infusion)
- SF-36, FSS, RHS (one week after infusion)
infusion speed to ensure the integrity of the blinding for patients. All patients were treated according to their individual established IVIg dosage prior to study entry. The infusion bag and the drip chamber were enclosed in a covering bag and a coloured infusion line was used so neither the assessor nor the patient was able to discern which brand was infused. The IVIg was infused at a standard safe infusion rate. To check whether blinding was maintained, both patients and the assessor were asked after the blind phase and at the end of the trial to guess which drug they thought had been administered in the blind phase.

Allocation was revealed after all patients had completed the study and data entry had been declared complete.

**Efficacy**

The primary objective was to study the efficacy of Kiovig compared to Gammagard S/D in the treatment of CIDP; the ODSS was used as the primary outcome measure. Before the trial started, we predefined in the protocol that a difference in the mean ODSS change from baseline between the two groups of ≥1 point was considered as equivalence. The two ODSS measurements, assessed immediately before infusion one (Gammagard) and two (first blinded infusion), were averaged and the mean value was taken as a baseline measurement. Changes in the vigorimeter values and the MRC sum score were used as secondary outcome measures as were all other measures.

**Safety**

The secondary objective was to compare the safety of both products. A questionnaire regarding AEs was completed by the patients during every infusion and again 1 week later. A neurologist blinded to the allocation of trial medication (EB, EC, AK) evaluated AEs by telephone at regular intervals.

**Statistical analysis**

The sample size calculation based on historical data showed a SD of 0.84 for ΔODSS (over a stable period of 2 months). To exclude differences of >1 point in ODSS, 11 patients were required in each treatment group (α=0.05, power 80%). The mean of ODSS changes from baseline for each of the four blinded infusions (infusions 3, 4, 5, 6) was compared using repeated measurements analysis of variance (ANOVA). As an operational criterion for equivalence, the 95% CI for the difference in the mean ODSS should not cross the values −1 and +1.

For all other outcome measures, the change from baseline was calculated by taking the mean of the scores during the double-blind phase and comparison was done with analysis of covariance (ANCOVA) with baseline value as covariate. Data were analysed according to the intention-to-treat principle.

All AEs were recorded. The statistical analysis for the objectives of the study was based upon data from the double-blind phase. The open-label Kiovig phase was primarily used to gain more safety information. The occurrences of AEs were compared using \( \chi^2 \) or Fisher exact test. Analysis was performed using SPSS V.15.0 and SAS V8.1.

**RESULTS**

From December 2007 to September 2008, 75 CIDP patients were screened for eligibility; 48 were excluded mainly because they were not treated with IVIg on a regular basis or had no signs of active disease (figure 2). Other reasons for non-eligibility were treatment in a different hospital than the neuromuscular centre where the diagnosis was established or treatment with another brand of IVIg (two patients). In total, 27 patients were rando-

In this study we compared the efficacy of a freeze-dried IVIg (Gammagard S/D) with a liquid preparation (Kiovig) for the treatment of CIDP. We found no significant difference in clinical efficacy as the 95% CI for the difference of mean ODSS was within the interval –1 to +1. Equivalence in this study was primarily based on the ability to carry out everyday functions measured using a disability scale (ODSS) validated in Guillain-Barré Syndrome (GBS) and CIDP.18 No significant differences were found between the two preparations for all other outcome measures, including impairment scales regarding muscle strength and sensory symptoms, and scales measuring handicap, fatigue, and quality of life.

### DISCUSSION

In this study we compared the efficacy of a freeze-dried IVIg (Gammagard S/D) with a liquid preparation (Kiovig) for the treatment of CIDP. We found no significant difference in clinical efficacy as the 95% CI for the difference of mean ODSS was within the interval –1 to +1. Equivalence in this study was primarily based on the ability to carry out everyday functions measured using a disability scale (ODSS) validated in Guillain-Barré Syndrome (GBS) and CIDP.18 No significant differences were found between the two preparations for all other outcome measures, including impairment scales regarding muscle strength and sensory symptoms, and scales measuring handicap, fatigue, and quality of life.

DF shown are differences from analysis of covariance with adjustment for baseline values with 95% CI and p value.

FSS, fatigue severity scale (range 0–7)—a higher score indicates more fatigue; ISS, INCAT sensory sum score (range 0–20)—a higher score indicates more sensory deficits; MRC, Medical Research Council (range 0–60)—a higher value indicates better muscle strength; ODSS, overall disability sum score (range 0–12)—a higher value indicates more limitations; RHS, Rotterdam handicap scale (range 9–36)—a higher score indicates less handicap; SF-36, short form (SF) health survey (all separate items range 0–100)—a higher score indicates better health or less bodily pain; Vigorimeter (range 0–160)—a higher value indicates better muscle strength.

Correctly that the 10% preparation was given; once because the infusion speed was accidentally somewhat faster than regular and in another case because the patient felt severely fatigued after the infusion. Thirteen patients had no idea what treatment they received in the blinded phase. Seven patients answered the treatment allocation question correctly and seven patients were incorrect.

### Treatment tolerance

Both IVIg brands were well tolerated. There were no significant differences between the two treatments in the number of commonly reported AEs except for the lower occurrence of cold shivers in patients randomised to Kiovig (table 3). Altogether, 4 out of 14 patients in the Kiovig treatment group versus 1 out of 13 patients in the Gammagard S/D group (p=0.33) reported their AEs to be ‘severe’ in the questionnaires. The number of patients who reported AEs to the blinded neurologist was similar in the two groups (8/14 in the Kiovig vs 7/13 in the Gammagard S/D group; p=0.86). Two patients, one in each treatment group, had a serious AE (requiring inpatient hospital stay), which was unrelated to the trial drug (elective surgery unrelated to CIDP). One patient had a mild allergic reaction to one of the blinded Kiovig infusions only needing treatment with an oral antihistamine. In the open label Kiovig phase, 14/27 patients reported AEs to the blinded neurologist. Half of these patients were treated in the blinded phase with Gammagard S/D the other half with Kiovig. No serious adverse events occurred in this open-label phase.

### Blinding

After the blinded and open-label phase, both patients and the assessor were asked which treatment they thought they had been administered during the blind phase to check if blinding had been successful. In 25 cases (95%) the assessor had no idea about the treatment that was given. In two cases the assessor thought incorrectly that the 10% preparation was given; once because the infusion speed was accidentally somewhat faster than regular and in another case because the patient felt severely fatigued after the infusion. Thirteen patients had no idea what treatment they received in the blinded phase. Seven patients answered the treatment allocation question correctly and seven patients were incorrect.
An in vitro model of immune neuropathy found a comparable efficacy of eight different IVIg products. A different response to various IVIg brands has been described in a randomised trial in primary immune deficiency. In Kawasaki disease, retrospective studies reported similar as well as different responses to various brands. An open study reported no clinical differences between Gammagard and Kiovig in MMN. As far as we know, no RCT has been published that evaluated differences between IVIg brands in neurological disorders.

The two preparations had similar AEs and there were no problems with the transition from one preparation to the other. Cold shivers were less common in patients treated with the brand, which might be caused by less aggregates and excipients in Kiovig. Aseptic meningitis or neutropenia as AEs after IVIg are reported to be unrelated to the proprietary formulation. A group of 50 healthy subjects showed no difference in tolerance to two different IVIg preparations including one liquid form. A retrospective study in Kawasaki disease reported more infusion-related rigors in one IVIg brand than in another.

Since one IVIg preparation was more concentrated (10%), it was not possible to blind the nurses who administered the trial drug because the IVIg dosage as well as the duration of administering had to be equal for both preparations. Therefore, the nurses were trained thoroughly in maintaining the blind. By asking the patients to report which drug they thought they had received we could show that blinding had been successful. Randomisation was successful as clinical characteristics were well-balanced between the treatment groups.

To ensure that the CIDP patients were still IVIg dependant they had to have had at least moderate disability in arms or legs at baseline or following IVIg reduction during the previous 12 months. Most patients additionally had at least some documented worsening of their CIDP within the 5–6 months before start of the study and some also had minor fluctuations in their clinical course after they had completed the trial. To make sure no IVIg refractory patients were included, only patients who initially improved after IVIg, being in a stable condition using a stable maintenance dose of IVIg and who were considered to need IVIg treatment were included.

Previous international trials regarding the efficacy of IVIg in CIDP used treatment periods of ≤6 weeks. Therefore, the double-blind treatment period of four infusions, administered over a time period of 6–16 weeks (mean 10 weeks) due to the different inter-individual intervals, seems reasonable as the half-life time of IVIg is about 5 weeks. Since we only compared two different IVIg brands manufactured by the same pharmaceutical company with each other, we can only draw conclusions about the equivalence of these two products. Logistically, it was not feasible to compare more available brands. However, our results suggest that the clinical effects of a new liquid IVIg product are similar to a non-liquid product that has been used for several decades.

In specific situations certain brands are recommended, such as IVIg preparations that contain less IgA in patients with a low IgA level and preparations containing less sucrose in patients with kidney disease. Liquid IVIg preparations do not need reconstitution prior to use and can potentially reduce the infusion time, but this was not investigated in this study.

Although some patients may prefer certain IVIg brands, this trial suggests that this is unlikely to be caused by differences in clinical efficacy or tolerance between a freeze-dried and a liquid product. As we showed no significant clinical differences between these two IVIg brands in their efficacy to treat CIDP it seems reasonable to assume that this will also apply for other diseases treated with IVIg.
