ABSTRACT

In lymph node (LN) proliferation centers in chronic lymphocytic leukemia (CLL), the environment protects from apoptotic and cytotoxic triggers. Here, we aimed to define the molecular basis for the increased drug resistance and searched for novel strategies to circumvent it. The situation in CLL LN could be mimicked by prolonged in vitro CD40 stimulation, which resulted in upregulation of anti-apoptotic Bcl-xL, A1/Bfl-1 and Mcl-1 proteins, and afforded resistance to various classes of drugs (fludarabine, bortezomib, roscovitine). CD40 stimulation also caused ERK-dependent reduction of BimEL protein, but ERK inhibition did not prevent drug resistance. Drugs combined with sublethal doses of the BH3-mimetic ABT-737 displayed partial and variable effects per individual CD40-stimulated CLL. The anti-apoptotic profile of CD40-triggered CLL resembled BCR-Abl-dependent changes seen in CML, which prompted application of c-Abl inhibitors imatinib or dasatinib. Both compounds, but especially dasatinib, prevented the entire anti-apoptotic CD40 program in CLL cells, and restored drug sensitivity. These effects also occurred in CLL samples with dysfunctional p53. Importantly, ex vivo CLL LN samples also displayed strong ERK activation together with high Bcl-xL and Mcl-1 but low BimEL levels. These data indicate that CLL cells in chemoresistant niches may be sensitive to therapeutic strategies that include c-Abl inhibitors.
INTRODUCTION

Chronic lymphocytic leukemia (CLL) is a CD5+ B-cell malignancy that is still considered incurable, although novel treatment combinations of monoclonal antibodies and chemotherapy¹ seem promising. Many patients eventually develop drug resistance through several pathways including mutation of the p53 tumor suppressor gene, or involving the gene encoding the ataxia telangiectasia mutated (ATM), which is a kinase required for p53 function. Such genetic lesions are uncommon in CLL at diagnosis, but increase in frequency as the disease progresses². Since the cytoreductive activity of most current chemotherapeutic agents requires functional p53, loss of p53 is associated with drug resistance and poor prognosis³. Because of these aspects, different agents with p53-independent modes of action are clearly needed.

CLL has been considered a smoldering disease characterized by long-lived tumor cells arrested in the G₀/G₁-phase of the cell cycle and possessing intrinsic apoptosis defects⁴. This concept was largely based on analyses of peripheral blood derived CLL cells. A study of in vivo cellular kinetics however suggested that CLL is a dynamic disease with substantial proliferation rates as well as increased death rates compared to normal B-cells⁵. Prior to this, it was already known that proliferation and especially increased survival of the malignant B-cells may not result primarily from intrinsic defects, but appear to depend largely on interactions with microenvironmental bystander cells. Interactions between CLL cells and follicular dendritic cells, bone marrow stromal cells, IL-6-producing endothelial cells, SDF-producing nurselike cells, or CD40L expressing CD4+ T cells⁶-⁹ have been shown to increase the apoptotic threshold in vitro. In a recent comparative survey of apoptosis regulatory genes and proteins in neoplastic B-cells derived from CLL lymph node (LN) proliferation centers and from peripheral blood¹⁰, we observed specific changes including increased expression of anti-apoptotic proteins such as Mcl-1, Bcl-xL and A1/Bfl-1 in LN cells.

Extended cell survival of tumor cells within the LN microenvironment may create an intracellular milieu permissive for genetic instability and for the accumulation of gene mutations that favors disease progression. Furthermore, these microenvironmental interactions may provide a safe haven from cytotoxic anticancer drugs, thus serving as a tumor reservoir from which relapse occurs (reviewed by Pedersen and Reed¹¹). This concept is supported by the observation that prolonged CD40 activation, which to a large extent recapitulates the anti-apoptotic expression profile of LN derived CLL cells, renders CLL cells resistant to current chemotherapeutics¹²,¹³. The currently widely applied drug fludarabine relies on an intact p53 response which induces expression of the Bcl-2 member Puma, thereby triggering apoptosis¹⁴-¹⁶. Alternative, p53-independent drugs such as the proteasome inhibitor bortezomib or the cyclin
dependent kinase inhibitor roscovitine engage other pro-apoptotic Bcl-2 members such as Noxa and Bim. Especially Bim is a potent pro-apoptosis member of the BH3-only subgroup of the Bcl-2 family, engaged by a variety of apoptotic triggers. A potential means of suppressing the lethal capacity of Bim involves the pro-survival kinase ERK. In model systems activation of ERK leads to phosphorylation and subsequent proteasomal degradation of the BimEL splice variant.

In the present study we used in vitro CD40 stimulation as a model for chemoresistant LN CLL, and searched for means to circumvent it. CD40 stimulation of CLL cells strongly induced Bcl-xL, Mcl-1 and A1/Bfl-1 proteins, resulting in a broad drug resistance. Various aspects of this anti-apoptotic program also occur in chronic myeloid leukemia (CML), a disease for which current treatment includes kinase inhibitors that were developed to target BCR-Abl signaling. Therefore, we next applied the c-Abl inhibitors imatinib (Gleevec, STI-571) or dasatinib (Sprycel, BMS-354825) in conjunction with CD40. Both drugs caused a profound reversal of the protective CD40 effects, and restored drug sensitivity. Probing of LN CLL samples demonstrated that in these protective niches similar pro-survival signaling pathways are active as upon CD40 triggering in vitro. Collectively, these data suggest that CLL cells residing in LN might be therapeutically targeted by drug combinations that include c-Abl inhibitors.

MATERIALS AND METHODS

Patient material
Patient material was obtained after routine diagnostic or follow-up procedures at the departments of Hematology and Pathology of the Academic Medical Center Amsterdam. This study was conducted after informed consent and approved by the AMC medical committee on human experimentation, in agreement with the Helsinki Declaration of 1975, revised in 1983. Lymph node (LN) material, diffusely infiltrated by CLL cells, was freshly frozen in liquid nitrogen directly after surgical removal. Immunohistochemical analysis of these lymph nodes revealed that greater than 90% of the tissue consisted of tumor cells. Peripheral blood (PB) mononuclear cells (PBMCs) of patients with CLL, obtained after Ficoll density gradient centrifugation (Pharmacia Biotech, Roosendaal, The Netherlands) were frozen in Iscove’s Modified Dulbecco’s Medium (IMDM) supplemented with L-Glutamine, 25 mM HEPES (Biowhittaker, Europe) containing, 2mM L-Glutamin (Invitrogen), 50 mg Gentamycin (Invitrogen) 3.57 x 10^{-4}% (v/v) β-mercapto ethanol (Merck, Darmstadt, Germany), 10

01-09-2008  11:08:27
% dimethyl sulphoxide (DMSO; Sigma Chemical Co., St. Louis, MO, USA) and 15% fetal calf serum, (FCS; ICN Biomedicals GnbH, Meckenheim, Germany), and stored in liquid nitrogen. Expression of CD5 and CD19 (antibodies obtained from Bekton Dickinson (BD) Biosciences, San Jose, CA, USA) on leukemic cells was assessed by flow cytometry (FACScalibur, BD Biosciences) and analysed with CellQuest software (BD Biosciences).

RNA isolation and RT-MLPA
Total RNA was isolated using the GenElute Mammalian Total RNA Miniprep Kit (Sigma Aldrich). Reverse transcription–multiplex ligation-dependent probe amplification assay (RT-MLPA) procedure was performed as described previously16,24.

Reagents
The proteasome inhibitor bortezomib was obtained from Janssen-Cilag (Tilburg the Netherlands). The γ-secretase inhibitor GSI-1, the Erk inhibitor PD-98059, the NF-κB inhibitor BAY-11-7082 and the proteasome inhibitor MG132 were obtained from Calbiochem (Amsterdam, the Netherlands). Roscovitine and fludarabine (F-Ara-A) were purchased from Sigma Chemical Co. (St. Louis, MO, USA). ABT-737 was obtained under MTA from Abbott (courtesy Dr S Rosenberg, Abbott Park, Illinois, USA). The kinase inhibitors, imatinib and dasatinib were from Novartis (Basel, Switzerland) and Bristol-Myers Squibb (New York, NY, USA) respectively.

Analysis of apoptosis, Western Blot and antibodies
For apoptosis induction, cells at a density of 1.5.10⁶/ml in culture medium were treated with 100 μM fludarabine (48 hrs), 30nM bortezomib, 25 μM roscovitine or 5 μM GSI1 (24 hrs), and stained with 200 nM MitoTracker Orange (Molecular Probes, Leiden, The Netherlands) for 30 minutes at 37°C and analysed by FACS. Western blotting was performed as described previously16. Cells were lysed in Laemmli Sample Buffer, and samples (10-30 μg protein) were separated by 13% sodium dodecyl sulfate polyacrylamide gel electrophoresis (10% gels for ERK). To screen for p53 functionality, cells were irradiated (5Gy) and after O/N incubation tested for the expression of p53 and p21 by western blot analysis as described before25. Blots were probed with polyclonal anti-Mcl-1 (catalog no. 554103; Pharmingen, BD Biosciences), monoclonal anti-Noxa (clone 114C307.1; Imgenex, San Diego, CA), monoclonal anti-Bim (clone 14A8; Chemicon, Temecula, CA), antiserum to β-actin (clone I-19; Santa Cruz Biotechnology, Santa Cruz, CA), polyclonal anti-Bcl-xL (catalog no. 620211, BD Biosciences), polyclonal anti-Bcl-2 (catalog no 210-701-C100, Kordia, Leiden...
the Netherlands) polyclonal anti-phospho-Erk (catalog no. #9102 Cell Signaling), polyclonal anti-Erk (catalog no. #9101 Cell Signaling), polyclonal antibodies against A1/Bfl-1 and Bid were a kind gift of Prof. Dr. J. Borst (The Netherlands Cancer Institute, Amsterdam, The Netherlands).

In vitro CD40 stimulation and cell lines
BCR-Abl positive K562 cells and NIH3T3 fibroblasts were cultured in IMDM as described above for CLL cells. CD40-ligand (CD40L, CD154) was expressed on NIH3T3 fibroblasts, stably transfected with a plasmid encoding human CD40L. Fibroblasts were irradiated (30Gy) and plated in culture-treated 6-wells plates (6x 10^5 cells/well). CLL cells were thawed and 5 x 10^6 cells per well were added to the adhered fibroblasts in 3 ml IMDM containing 10% FCS and incubated for 48 hrs at 37°c. To test the effect of c-Abl kinase inhibitors, imatinib and dasatinib, and the effect of Erk-inhibitor PD-58059, CLL cells were pre-treated with 80 μM imatinib or dasatinib, or 50 μM PD-58059 for 30 minutes. After pre-incubation CLL cells were stimulated for 48 hrs at 37°c with CD40L with or without 30 μM imatinib or dasatinib or 50 μM PD-58059. In the case of dasatinib, also other regimens and concentrations were used, where CLL cells were first co-cultured for 48 hrs with CD40L-expressing or control 3T3 fibroblasts, detached and washed and subsequently incubated in medium for an additional 48 hrs in the presence of varying dasatinib concentrations (30nM-30μM), followed by testing sensitivity to cytotoxic drugs, as described above.

RESULTS

Prolonged CD40 stimulation of CLL cells results in broad drug resistance, which is independent of ERK-mediated decrease in BimEL levels

In vitro stimulation via CD40 renders CLL cells resistant to fludarabine and induces expression of various anti-apoptotic proteins such as Bcl-xL and A1/Bfl-1 via de novo transcription. In addition to previously described transcriptional effects of prolonged CD40 triggering, several novel effects on protein levels of various apoptosis regulators were observed. In particular, the Bim EL splice variant decreased while Mcl-1 levels increased (see Fig. 1A).

Since it is known that ERK signaling can affect Bim EL protein levels in model systems this aspect was investigated further. Over the course of several days of CD40 stimulation, a significant reduction in Bim EL protein levels occurred, although Bim mRNA levels remained constant (see also Fig. 4 below). In Figure 1B, the larger
two Bim species represent Bim\textsubscript{EL} and most presumably a splice variant Bim\textalpha\textsubscript{128}, which became visible in certain samples upon prolonged migration in SDS-PAGE. Under the experimental conditions applied a short-lived phosphorylated form of Bim (p-Bim) is probably also present\textsuperscript{21}, but in our hands this form of Bim could not be observed in primary samples either with the antibody used here, nor with commercial antibodies specifically generated against p-Bim. The activation status of ERK upon CD40 triggering was increased, and addition of the specific ERK inhibitor PD-98059 during CD40 stimulation prevented the reduction of Bim\textsubscript{EL} (Fig. 1C). Addition of the proteaseome inhibitor MG132 after CD40 stimulation demonstrated that Bim\textsubscript{EL} levels were controlled via increased protein turnover, confirming previous reports\textsuperscript{21,22,29} (data not shown).

Next, CLL cells triggered via CD40 in the absence or presence of ERK inhibition were
investigated for sensitivity to drugs that are in current clinical use or in preclinical development. As can be seen in figure 2, prolonged CD40 stimulation rendered the cells resistant to fludarabine, as observed before\textsuperscript{12,13}, the proteasome inhibitor bortezomib and the cyclin-dependent kinase inhibitor roscovitine. In addition, the $\gamma$-secretase inhibitor GSI-1 was included, which is considered to be an inhibitor of Notch signaling\textsuperscript{30}. We have recently observed that GSI-1 is in fact an inhibitor of the proteasome and a potent inducer of apoptosis in CLL (Hallaert et al., submitted). CD40 triggering also rendered CLL cells resistant to GSI-1. For multiple CLL isolates tested, addition of ERK inhibitors did not alleviate the broad drug resistance afforded via prolonged CD40 stimulation (Fig. 2). Together these data indicate that although CD40 signaling activates ERK and thereby causes a decline in Bim$_{EL}$ levels, this is not the cause for the observed broad drug resistance.

**c-Abl inhibitors prevent the anti-apoptotic protein profile of CD40-treated CLL cells**

Another aspect of prolonged CD40 triggering of CLL cells was an increase in Mcl-1 protein (see Fig. 1A) which was, similar to the changes in Bim, independent from increased transcription (see also below). Mcl-1 has recently been recognized as promising target for drugs\textsuperscript{31}, and has been implicated in anti-apoptotic signaling via BCR-Abl in chronic myeloid leukemia\textsuperscript{32-34}. Furthermore, other anti-apoptotic changes

---

**Figure 2. Broad drug resistance of CLL cells upon CD40 stimulation is not prevented by ERK inhibition.**

CLL cells were co-cultured with control 3T3 (control) or CD40L-expressing cells for 48 hrs, in the presence of ERK inhibitor PD-98059 as indicated. After detachment and washing, cells were incubated with the indicated drugs as described in detail in Methods, and analyzed for apoptosis by MitoTracker staining after 24 hrs (roscovitine, bortezomib and GSI-1) or 48 hrs (fludarabine). Cells cultured on 3T3 cells (black bars) are sensitive to all drugs, but CD40 stimulation (white bars) confers broad drug resistance and this is maintained when ERK is inhibited (grey bars). The data shown for untreated samples (medium) were measured at 24hr. Apoptosis levels of medium samples at 48hrs were comparable.
in our \textit{in vitro} CD40-CLL system, such as increased Bcl-xL and decreased Bim, have also been implicated in BCR-Abl signaling\textsuperscript{32,35-37}. Lastly, it was recently reported that c-Abl protein expression correlates positively with tumor burden and disease stage in CLL\textsuperscript{38}. Therefore, we next tested the c-Abl inhibitor STI-571/gleevec/imatinib as a potential suppressor of CD40-mediated pro-survival effects in CLL cells. In figure 3 it can be seen that imatinib caused a clear reversal of almost all effects of CD40 stimulation regarding Bcl-xL, Mcl-1, A1/Bfl-1 and Bim\textsubscript{EL} levels (left panel). This was also observed for the second generation Abl inhibitor sprycel/dasatinib (middle panel).

\begin{figure}
\centering
\includegraphics[width=\textwidth]{figure3.png}
\caption{Anti-apoptotic gene and protein profile of CLL induced by CD40 stimulation is reversed by kinase inhibitors imatinib and dasatinib.}
\end{figure}

\textbf{(A)} CLL cells were co-cultured with control 3T3 or CD40L-expressing cells for 48 hrs, in the presence of PD-98059, imatinib or dasatinib as indicated. Lysates were probed for Bim, Mcl-1, Bcl-xL, A1/Bfl-1 and Bcl-2 as indicated and actin as loading control. Shown are representative examples of 2 CLL samples with WT p53 function (left and middle panel), and 1 CLL with p53 dysfunction (right panel; note different order of samples). The upregulation of Mcl-1, Bcl-xL and A1/Bfl-1 is not affected by ERK inhibition, but prevented by imatinib or dasatinib, irrespective of p53 functionality.

\textbf{(B)} RNA was collected from CLL cells stimulated for 48 hrs with CD40 and inhibitors as indicated, and assayed for expression of 34 apoptosis genes by MLPA. Shown are averaged relative expression levels \pm SD (in percentage of total normalized signal) of selected genes in samples from p53 WT (n=4) and p53 dysfunctional (n=3) CLL cells. The CD40-mediated positive effects on transcription of A1/Bfl-1 and Bcl-xL are reversed by Abl kinase inhibitors. Examples of genes that are not significantly affected at the transcriptional level are Mcl-1, Bim and GUS (\(\beta\)-Glucuronidase, a housekeeping gene).
This compound has a higher specific activity towards c-Abl, but is also less specific for Abl kinase and targets other kinases such as Btk, Lyn and Tec. The effects of imatinib and dasatinib with respect to reversing the CD40 effects on pro-survival parameters were also observed in CLL cells with a dysfunction in the p53 pathway (Fig. 3, right panel).

The various kinase inhibitors were also monitored for their effects on transcription using a multiplex assay able to quantify expression of 34 apoptosis regulatory genes. As described previously, prolonged in vitro CD40 stimulation of CLL cells induces transcription of Bcl-xL and A1/Bfl-1, as well as a reduction in Noxa. For the ERK inhibitor PD-98059 no effects on transcription of these genes were found. In contrast, the c-Abl inhibitors prevented upregulation of Bcl-xL and A1/Bfl-1 transcripts, while for example Mcl-1 and Bim transcripts were hardly affected by these drugs (Fig. 3B black bars), although they did display changes at the protein level (Fig. 3A). The effects of the Abl kinase inhibitors on Bcl-xL and A1/Bfl-1 were similar to those observed when CLL cells were exposed to NF-κB inhibitor BAY-11-7082 during stimulation via CD40 (Supplementary Fig. 1). The inhibitory effects of especially dasatinib on Bcl-xL and A1/Bfl-1 transcription were also detected in cells with a dysfunctional p53 response (Fig. 3B white bars). In these cases, the effects of imatinib on CD40-induced gene transcription were limited, suggesting that perhaps the suppressive effects of imatinib may require p53 function. The complete dataset for all genes interrogated by the MLPA probe set is represented in supplementary figure 2. Together these data demonstrate that imatinib/dasatinib have a clear impact on signaling pathways leading to gene transcription such as NF-κB, and also on mechanisms controlling protein turnover of Mcl-1 and Bim.

Contribution to drug resistance of pro-survival proteins probed by ABT-737

Anti-apoptotic Bcl-2 family members can be counteracted by BH3 mimetics such as ABT-737, a widely studied compound in preclinical development. ABT-737 is very effective against Bcl-2 and Bcl-xL, but does not bind to Mcl-1 or A1/Bfl-1. As reported before, CLL cells are quite sensitive to ABT-737, but upon stimulation with CD40 this is reduced approximately 100-fold (Fig. 4 A&B). We tested whether sublethal doses of ABT-737 could synergize with other drugs in this setting. There was a slight increase in apoptosis of CD40-stimulated cells when 0.1 μM ABT-737 was combined with various other drugs. This was further restored to levels observed in medium or control cultures with 3T3 cells by using 1 μM ABT-737. In figure 4C the averaged data from 4 CLL patients are shown. Individual sample responses to
ABT-737 showed divergent patterns, with some patient's cells displaying full reversal of drug sensitivity at 1.0 μM ABT-737 for all drugs tested, while others displayed different patterns depending on the drug tested (Supplemental Fig. 3). This seemed consistent with the clear patient to patient variation in the degree of upregulation of Mcl-1 and A1/Bfl-1 (Fig. 3A). These results indicate that the contribution of Bcl-2 and Bcl-xL to the observed drug resistance in this in vitro model is substantial, but could generally be counteracted by ABT-737. The efficiency and effective dose with which ABT-737 acts differs per patient sample and this probably correlates with the degree of increase in Mcl-1, and possibly A1/Bfl-1, obtained with CD40 stimulation.

**c-Abl kinase inhibitors prevent drug resistance of CD40-treated CLL cells**

In a similar fashion as above for ABT-737, the effect of c-Abl kinase inhibitors on the drug resistance afforded by CD40 triggering was measured. The apoptosis-inducing effects of the Abl inhibitors themselves on control samples co-cultured with 3T3 cells and CD40L-expressing cells were minimal (Fig. 5A, medium samples). Only at high
levels and upon prolonged exposure did imatinib and dasatinib induce significant apoptosis in CLL cells, in contrast to e.g. K562 cells which are very sensitive due to their dependence on the BCR-Abl fusion protein for survival (Supplemental Fig. 4). Remarkably however, imatinib and especially dasatinib prevented the resistance towards various drugs normally observed upon CD40 treatment of CLL cells. This appeared true for CLL samples with mutated as well as unmutated IgV\textsubscript{H} gene sequences (both n=2). The sensitising effect of these inhibitors was also seen in CLL cells with a dysfunctional p53 pathway (Fig. 5B). Especially the cytotoxic effect of

**Figure 5. Drug resistance of CD40-stimulated CLL cells is reversed by c-Abl kinase inhibitors.**

(A) CLL samples (n=4) were cultured on 3T3 (control) or CD40L-expressing cells in the presence of the indicated inhibitors for 48 hrs, and after detachment and washing cultured for 24 hrs in medium or with the cytotoxic drugs. Average results for apoptosis measured via MitoTracker staining are shown.

(B) The same as in A) for an experiment with p53 dysfunctional cells. Data are representative for 3 similar experiments performed; the variation among samples in particular for background apoptosis in the absence of external stimuli precluded averaging.

(C) A similar experiment as in A) was performed with decreasing concentrations of dasatinib as indicated. Drug susceptibility was assessed by incubation with 5 \(\mu\)M GSI-1 for 24 hrs. Results represent averages of 4 experiments or 2 where indicated. At 3 nM there was no effect of dasatinib detectable (not shown).

(D) Sequential CD40 stimulation followed by incubation with c-Abl kinase inhibitors. CLL cells were co-cultured with 3T3 cells expressing CD40L for 48 hrs, detached and washed before addition of dasatinib (300 nM) for an additional 48 hrs, and were then tested for drug susceptibility. Results represent average data of 3 experiments.
proteasome inhibitors (bortezomib and GSI-1) was potentiated by treatment of CLL cells with c-Abl inhibitors during CD40 exposure. In general, the effects of dasatinib were stronger than those of imatinib at the concentrations used (30 μM), as was also observed for the effects on protein levels (see Fig. 3). Since dasatinib has a higher specific activity towards its target kinases than imatinib\(^{23,43}\) we also tested its effects over a lower range of concentrations (30nM-3μM). This is demonstrated in figure 5C for the results obtained with GSI-1, which was in general the strongest inducer of apoptosis in CLL cells among the drugs tested.

The results thusfar were obtained with simultaneous administration of CD40 signals and kinase inhibitors. To better reflect the actual situation of LN CLL cells already exposed to a protective environment, isolated PB CLL cells were first stimulated via CD40 for 48 hrs, followed by separate addition of dasatinib (0.3μM) and drug-sensitivity tests. Also in this set-up, a reversal of resistance towards various drugs (fludarabine, bortezomib, roscovitine) could be observed (Fig. 5D). Thus, dasatinib has a clear capacity to interfere with the protective effects afforded by prolonged CD40 stimulation.

**Similar apoptosis protein signature in ex vivo LN samples as upon in vitro CD40 triggering**

To relate the effects of *in vitro* CD40 stimulation with the *in vivo* situation, samples from CLL lymph nodes were lysed directly in SDS-containing sample buffer and probed for the presence of proteins involved in apoptosis regulation. As observed before, a clear increase of Bcl-xL protein was present in LN samples compared to peripheral blood (PB) samples\(^{10}\). This was also found for Mcl-1\(^{10}\) and A1/Bfl-1 (data not shown). Regarding the expression levels of other signature proteins involved in CD40-mediated anti-apoptosis pathways, a strong increase in both total and phosphorylated ERK was found, concomitant with decreased levels of Bim\(_{EL}\) (Fig. 6). These findings indicate that in CLL lymph nodes similar survival pathways are operational as those that can be induced in peripheral blood CLL cells by prolonged *in vitro* CD40 stimulation.
DISCUSSION

Previous reports have described effects of inhibitors of BCR-Abl kinase on single anti-apoptosis proteins (predominantly Mcl-1, Bcl-xL or Bim) in CML or model cell lines. This study provides an overview on the effects of c-Abl inhibitors on all Bcl-2 members in the context of CD40 signaling in CLL cells. The rationale for the present study was two-fold. First, there is the growing concept that CLL is a dynamic disease, with proliferation centers in LN and possibly also BM. These protective niches, where cells are prone to be more drug resistant, are presumably the source of relapsing clones. Second, the potential of novel drugs such as kinase inhibitors, to target pro-survival signaling pathways to which malignant cells have become addicted.

We have observed that our in vitro CLL culture model setting provides strong and probably supra-physiological CD40 signals, with longlasting protective effects which continue after detachment of CLL cells from CD40L cells (data not shown). Nevertheless, comparison between LN samples and PB CLL cells stimulated in vitro via CD40 indicated the presence of a comparable pro-survival signature as implied by ERK activation and BimEL levels. Previously, we have shown that in LN samples also increased levels of Bcl-xL and Mcl-1 are detectable. Together, the available data indicate that the pro-survival signature triggered via CD40 stimulation in vitro is also found in CLL lymph nodes, and imply that our experimental data hold promise for extrapolation towards a therapeutic setting.

With respect to post-transcriptional effects of CD40 stimulation on CLL cells, both Bim and Mcl-1 proteins are known targets for phosphorylation and subsequent increased proteasomal degradation. Cytokine withdrawal in murine cell lines causes decreased PI3K-Akt/PKB signaling to activate GSK3 which in turn phosphorylates Mcl-1, thus marking it for proteasomal degradation. In the case of CLL cells, our data indicate that upon CD40 stimulation PKB phosphorylation was undetectable, the PI3 kinase
inhibitor LY294002 did not trigger apoptosis, and the rate of Mcl-1 protein turnover was
not changed (unpublished observations). Since Mcl-1 transcription in CLL cells was
also not affected by CD40, this suggests that the increase in Mcl-1 protein is possibly
controlled at the level of translation by a non-PKB dependent mechanism. Recent
evidence from other experimental systems indeed points at translational repression
of Mcl-1 via eIF initiation factors as yet another point of regulation\textsuperscript{45,46}. If this system
is operational under our experimental conditions and whether it may be connected
with the other recently described pathway implicating antigen receptor/PI3-K/PKB
signaling in affecting Mcl-1 levels\textsuperscript{47} remains to be determined. In contrast to the
situation in AML cells\textsuperscript{41}, in primary CLL cells the ERK pathway seems not responsible
for increased Mcl-1 protein, as the ERK inhibitor PD-98059 did not block its increase,
and did not affect drug susceptibility (Fig. 2&3). Whether or not increased Mcl-1 plays
an important role \textit{in vivo} in survival of CLL in lymph nodes seems an important issue
with respect to therapeutic application of ABT-737. Our data and those of others\textsuperscript{31,41}
indicate that variations in Mcl-1 and possibly also A1/Bfl-1 levels will determine the
effective dose of ABT-737 both as a single agent and in drug combinations. Of note,
the combination of ABT-737 with roscovitine, which should counteract Bcl-2, Bcl-xL as
well as Mcl-1\textsuperscript{31}, was not effective in all patients (Supplemental Fig. 4). This suggests
that either roscovitine is unable to reduce Mcl-1 in this setting or that perhaps in these
samples A1/Bfl-1 is a dominant factor. Our observations on increased Bim\textsubscript{EL} turnover
are in accord with an established pathway of ERK-mediated phosphorylation and
proteasomal degradation\textsuperscript{21,22,29}. To our knowledge, this is the first example of this
pathway operating in primary tumor cells upon CD40 stimulation, and in CLL LN
samples.

In our experience, neither imatinib nor dasatinib are efficient inducers of apoptosis as
single agents, in contrast to their effects on K562 cells, which depend for survival on
the BCR-Abl fusion oncogene (Supplemental Fig. 3). In a recent study, considerable
variation in apoptosis susceptibility in untreated and dasatinib-treated peripheral
blood samples was found using 5 µM dasatinib, and the response was correlated
with IgV\textsubscript{H} mutation and ZAP70 status\textsuperscript{48}. This and other studies performed to date
agree that, in CLL cells from peripheral blood, dasatinib has a strong synergistic
effect in combination with p53-pathway dependent and -independent agents\textsuperscript{48-50}.
Transcriptional effects of imatinib and dasatinib on Bcl-xL and A1/Bfl-1 were similar
to those of inhibitors of NF-κB. We noted that the effects of the c-Abl inhibitors on
reversing ERK phosphorylation status, and the corresponding changes in Bim\textsubscript{EL}
levels varied among patients, without apparent correlation with prognostic factors
such as mutation or p53 status (data not shown and Fig. 3). These signaling
pathways are affected/reversed by imatinib and dasatinib although the actual
target(s) remains unknown. Recent analyses of the spectrum of kinase targets of these compounds points to various candidates involved in T- and/or B-cell activation such as Src kinases including Lck and Fyn, Btk and Tec kinase\textsuperscript{23,39}. The spectrum of non-Abl kinases targeted by dasatinib is in fact quite broad (>20 kinases), and an immunosuppressive effect was predicted\textsuperscript{23}, and recently confirmed for T cells\textsuperscript{51}. Our preliminary analyses do not show a similar inhibitory effect of dasatinib on \textit{in vitro} B-cell proliferation however (A. Jaspers, unpublished observation). From the kinases targeted by dasatinib no obvious candidate(s) for exclusive participation in the CD40 pathway is apparent, although the Ser/Thr kinase p38\textsubscript{a} and upstream MAP kinases appear likely as participants. A clue for the participation of Btk or Tec kinases comes from a recent report that their expression level is regulated via NF-κB in a positive feedback-loop. This loop can be interrupted by proteasome inhibitors\textsuperscript{52}, which fits with our observation that the combination of bortezomib or GSI-1 with dasatinib has the strongest effect on apoptosis of CD40-stimulated CLL cells (Fig. 5A&B).

Obviously, c-Abl kinase itself may very well be involved, and there is evidence that levels of c-Abl protein expression correlate positively with tumor burden and disease stage in CLL\textsuperscript{53}. Another study reported that c-Abl becomes active upon CD40 triggering and then induces p73\textsuperscript{54}. This signaling route is predicted to bypass p53 and may therefore be therapeutically relevant. Both these studies used imatinib and/or introduction of recombinant c-Abl, so they cannot provide definitive evidence of endogenous c-Abl kinase activity in CLL. The majority of studies on activity have been done with the BCR-Abl-positive cell line K562 or primary CML samples where expression levels of the oncogenic fusion protein are augmented. Our preliminary efforts to detect active endogenous c-Abl either in un-stimulated, CD40-triggered or LN CLL cells by western blotting with commercial antibodies were inconsistent.

At present, two independent mechanisms are attributed to the development of chemoresistance in CLL. The first is a shift in the balance between pro- and anti-apoptotic regulators, and both Mcl-1\textsuperscript{55} and Bfl-1/A1\textsuperscript{56} have been associated with resistance to chemotherapy. Significantly, these hallmarks are very similar to the CD40-activated CLL phenotype we use as a model. The second mechanism is based on acquired mutations resulting in a dysfunctional p53 response\textsuperscript{3}. A recent phase II evaluation of dasatinib as single agent in relapsed and refractory CLL showed limited effects, but in good correlation with our data a reduction of lymph node size was observed in a major fraction of patients\textsuperscript{57}. Our data indicate that c-Abl inhibitors, notably dasatinib, overcome the protective profile within the micro-environment resulting in susceptibility to p53 pathway dependent drugs (fludarabine) as well as to p53-independent agents (roscovitine, bortezomib, ABT-737). Thus, from a clinical perspective it may be more effective to apply combination strategies of dasatinib
with other drugs. Our data provide a rationale to combine dasatinib both with purine-analogues but also with drug regimens that do not exclusively rely on p53 function for efficacy.

ACKNOWLEDGEMENTS

We thank Dr. M. Kramer, Dr. S. Wittebol, (department of Internal Medicine, Meander Medical Centre, Amersfoort) and Dr. J. Baars (department of Internal Medicine, The Netherlands Cancer Institute, Amsterdam) for including CLL patients in this study, and René van Lier for his insightful comments and critical reading of the manuscript. This work was supported by the Dutch Cancer Foundation (DCF) grant nr. UVA2004-3039. A.P.K. is supported by a ‘Veni’ grant from ZonMw (The Netherlands Organization for Health Research and Development).

</table>

\(^1\) Patient data for the lymph node samples used in this study can be found in ref 10.
\(^2\) Percentage of cells positive for CD5 and CD19 surface expression.
\(^3\) Mutated IgV\(_H\) gene (+) denotes >2% mutations compared to germline sequence.
\(^4\) P53 functional status was measured via radiation-induced RNA expression of p53 target genes Puma and Bax, or by p53 and p21 protein upregulation via western blot, as described in refs 16 and 25. Patient 25 had a so-called type A dysfunction. (ND = not determined)
\(^5\) As determined by FISH. Probes for 11q22.3 (ATM), 13q14 (D13S319) and 17p13 (TP53) were obtained from Abbott-Vysis. Samples with >10% aberrant signals were considered abnormal.

SUPPLEMENTAL FIGURE LEGENDS

Figure S1. NF-κB inhibitor BAY-11-7082 blocks CD40-mediated Bcl-xL and Bfl-1 upregulation. CLL cells were stimulated with or without CD40L for 48 hrs in the presence of ERK inhibitor PD-98059 or of BAY-11-7082, an irreversible inhibitor of IκB-α phosphorylation (1 and 5 μM). Cells were lysed in SDS-containing buffer and analyzed by western blot.

Figure S2. RT-MLPA analysis of p53 WT and p53 dysfunctional CLL cells, stimulated via CD40 in absence or presence of kinase inhibitors. Cells were stimulated for 48 hrs as in figure 3b, and apoptotic gene expression profile was analyzed by RT-MLPA. Results were normalized and expressed relative to total signal. Housekeeping genes included in this assay were, GUS, B2M, FLT and PARN. (Note that probes for IAP2 are non functional). Graphs represent averaged data ± SD of n=4 p53 functional (A) and n=3 dysfunctional (B) samples.
Figure S3. Apoptosis sensitivity of individual CLL samples after co-culture with 3T3 or 3T40L cells, followed by treatment with various drugs in conjunction with ABT-737. CLL samples were cultured as described in legend to figure 4, followed by incubation with the indicated drugs in the presence of 1μM ABT-737. Apoptosis was determined after 24 hrs by Mito Tracker staining.

Figure S4. Peripheral blood-derived and CD40-stimulated CLL cells are insensitive to imatinib or dasatinib. (A,B) Peripheral blood-derived CLL cells (n=3) were stimulated with increasing concentration of imatinib or dasatinib for 24, 48 or 72 hrs. (C,D) CLL cells (n=4) were cultured for 48 hrs in medium or together with 3T3, or 3T40L cells, followed by stimulation with different concentrations imatinib or dasatinib for 48 hrs. The BCR-Abl positive cell line K562 was used as a positive control for imatinib and dasatinib-induced apoptosis. Apoptosis was determined by MitoTracker staining.
