Search for events with large missing transverse momentum, jets, and at least two tau leptons in 7 TeV proton–proton collision data with the ATLAS detector

ATLAS Collaboration

1. Introduction

Supersymmetry (SUSY) [1−5] introduces a symmetry between fermions and bosons, resulting in a SUSY partner (sparticle) for each Standard Model (SM) particle with identical mass and quantum numbers except a difference by half a unit of spin. As none of these sparticles have been observed, SUSY must be a broken symmetry if realised in nature. Assuming R-parity conservation [6,7], sparticles are produced in pairs. These would then decay through cascades involving other sparticles until the lightest SUSY particle (LSP) is produced, which is stable.

Minimal gauge-mediated supersymmetry breaking (GMSB) [8–11] models can be described by six parameters: the SUSY breaking mass scale felt by the low-energy sector (Λ), the messenger mass (Mess), the number of SU(5) messengers (N5), the ratio of the vacuum expectation values of the two Higgs doublets ($\tan \beta$), the Higgs sector mixing parameter ($\mu$) and the scale factor for the gravitino mass ($C_{grav}$). In this analysis Λ and $\tan \beta$ are treated as free parameters and the other parameters are fixed to $M_{mess} = 250$ TeV, $N_5 = 3$, $\mu > 0$ and $C_{grav} = 1$, similar to other GMSB benchmark points in the literature, e.g. G2a [14] and SP57 [15]. The $C_{grav}$ parameter determines the lifetime of the next-to-lightest SUSY particle (NLSP). For $C_{grav} = 1$ the NLSP decays promptly ($C_{grav} \ll 0.1$ mm). With these parameters, the production of squark and/or gluino pairs is expected to dominate at the present Large Hadron Collider (LHC) energy. These sparticles decay directly or through cascades into the NLSP, which subsequently decays into the LSP. In GMSB models, the LSP is the very light gravitino ($\tilde{G}$). Due to the gravitino’s very small mass of $O$(keV), the NLSP is the only sparticle decaying into the LSP. This leads to multiple jets and missing transverse momentum ($E_{T}^{miss}$) in the final states. The experimental signature is then largely determined by the nature of the NLSP, which can be either the lightest stau ($\tilde{\tau}_1$), a right-handed slepton ($\tilde{\ell}_R$), the lightest neutralino ($\tilde{\chi}_1^0$) or a sneutrino ($\tilde{\nu}$), leading to final states containing taus, light leptons ($e, \mu$), photons, b-jets, or neutrinos. For $N_5 = 3$ the $\tilde{\tau}_1$ and $\tilde{\ell}_R$ NLSPs become more dominant compared to lower values of $N_5$. At large values of $\tan \beta$, the $\tilde{\tau}_1$ is the NLSP for most of the parameter space, which leads to final states containing between two and four tau leptons. In the so-called CoNLSP [16] region, the mass difference between the $\tilde{\tau}_1$ and the $\tilde{\ell}_R$ is smaller than the tau lepton mass such that both sparticles decay directly into the LSP and are therefore NLSP.

This Letter reports on the search for events with large $E_{T}^{miss}$, jets, and at least two hadronically decaying tau leptons. The analysis has been performed using 2 $fb^{-1}$ of proton–proton ($pp$) collision data at $\sqrt{s} = 7$ TeV recorded with the ATLAS detector at the LHC between March and August 2011. Although the analysis is sensitive to a wide variety of models for physics beyond the Standard Model, the results shown here are interpreted in the context of a minimal GMSB model. The three LEP Collaborations ALEPH [17], DELPHI [18] and OPAL [19] studied $\tilde{\tau}_1$ pair production, with the subsequent decay $\tilde{\tau}_1 \rightarrow \tau \tilde{G}$ in the minimal GMSB model. The best limits are set by the OPAL Collaboration and $\tilde{\tau}_1$ NLSPs with masses below 87.4 GeV are excluded. A limit on the SUSY breaking mass scale $\Lambda$ of 26 TeV was set for $N_5 = 3$, $M_{mess} = 250$ TeV, independent of $\tan \beta$ and the NLSP lifetime. The CMS Collaboration searched for new physics in same-sign ditau events [20] and multiparticle events including ditau [21] using 35 pb$^{-1}$ of data, but the minimal GMSB model was not considered. A search for supersymmetry in final states containing at least one hadronically decaying tau lepton in 7 TeV proton–proton collision data with the ATLAS detector...
identified as isolated tracks with a corresponding energy deposit in the electromagnetic calorimeter. The selection criteria applied to muons and “medium” quality electrons are described in more detail in Refs. [51] and [52], respectively.

The measurement of the missing transverse momentum two-dimensional vector \( p_T^{\text{miss}} \) (and its magnitude \( E_T^{\text{miss}} \)) is based on the transverse momenta of identified jets, electrons, muons and all calorimeter clusters with \(|y| < 4.5\) not associated to such objects [53]. For the purpose of the measurement of \( E_T^{\text{miss}} \), taus are not distinguished from jets.

In this search, only hadronically decaying taus are considered. The tau reconstruction is seeded from anti-\( k_L \) jets with \( p_T > 10 \text{ GeV} \). An \( \eta \) - and \( p_T \)-dependent energy calibration to the hadronic tau energy scale is applied. Hadronic tau identification is based on observables sensitive to the transverse and longitudinal shape of the calorimeter shower and on tracking information, combined in a boosted decision tree (BDT) discriminator [54]. Transverse radiation and calorimeter information is used to veto electrons misidentified as taus. A tau candidate must have \( p_T > 20 \text{ GeV} \), \(|\eta| < 2.5\), and one or three associated tracks of \( p_T > 1 \text{ GeV} \) with a charge sum of \( \pm 1 \). The efficiency of the BDT tau identification (the “loose” working point in Ref. [54]), determined using \( Z \to \tau \tau \) events, is about 60\%, independent of \( p_T \), with a jet background rejection factor of 20–50.

During a part of the data-taking period, an electronics failure in the LAr barrel EM calorimeter created a dead region in the second and third layers, corresponding to approximately 1.4 x 0.2 radians in \( \Delta \eta \times \Delta \phi \). Electron and tau candidates falling in this region are discarded. A correction to the jet energy is made using the energy depositions in the cells neighbour the dead region; events having at least one jet for which the energy after correction is above 30 GeV are discarded, resulting in a loss of \( \sim 6\% \) of the data sample.

5. Data analysis

The analysed data sample, after applying beam, detector and data-quality requirements, corresponds to an integrated luminosity of \((2.05 \pm 0.08) \text{ fb}^{-1} \) [55,56]. Candidate events are pre-selected by a trigger requiring a leading jet, i.e., the jet having the highest transverse momentum of all jets in the event, with \( p_T > 75 \text{ GeV} \), measured at the raw electromagnetic scale, and \( E_T^{\text{miss}} > 45 \text{ GeV} \) [57]. In the offline analysis, these events are required to have a reconstructed primary vertex with at least five tracks, a leading jet with \( p_T > 130 \text{ GeV} \) and \( E_T^{\text{miss}} > 130 \text{ GeV} \). These requirements ensure a uniform trigger efficiency that exceeds 98\%.

Pre-selected events are then required to have at least two identified tau candidates and must not contain any electron or muon candidates with transverse momenta above 20 GeV or 10 GeV, respectively. To suppress soft multi-jet events, a second jet with \( p_T > 30 \text{ GeV} \) is required. The \( p_T \) spectrum of the leading tau candidate after pre-selection of candidate events, soft multi-jet rejection and the requirement of two or more taus and no light leptons is shown in Fig. 1.

This selection rejects almost all soft multi-jet background events. Remaining multi-jet events, where highly energetic jets are mis-measured, are rejected by requiring the azimuthal angle between the missing transverse momentum and either of the two leading jets \( \Delta \phi (p_T^{\text{miss}}, \text{jet}_{i,2}) \) to be larger than 0.4 radians.

The SR is defined by requiring \( m_{\text{eff}} > 700 \text{ GeV} \) and \( m_{\text{off}}^2 + m_{\text{jet}}^2 > 80 \text{ GeV} \), where \( m_{\text{eff}} \) is the effective mass\(^2\) and \( m_{\text{jet}}^2 + m_{\text{off}}^2 \) is the

---

1. ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the centre of the detector and the z-axis along the beam pipe. The x-axis points from the IP to the centre of the LHC ring and the y-axis points upward. Cylindrical coordinates \((r, \phi)\) are used in the transverse plane, \( \phi \) being the azimuthal angle around the beam pipe. The pseudorapidity is defined in terms of the polar angle \( \theta \) as \( \eta = -\ln \tan(\theta/2) \).

2. The effective mass \( m_{\text{eff}} \) is calculated as the sum of \( E_T^{\text{miss}} \) and the magnitude of the transverse momenta of the two highest-\( p_T \) jets and all selected taus.
sum of the transverse masses\(^3\) of the two leading tau candidates. The \(m_{\text{eff}}\) distribution after the \(\Delta\phi(p_{T,\text{miss}}^\tau, \text{jet}_1, 2)\) requirement and the \(m_1^\tau + m_2^\tau\) distribution after the \(m_{\text{eff}}\) requirement are shown in Fig. 2. After applying all the analysis requirements, 3 events are selected in the data.

6. Background estimation

The dominant backgrounds in the SR arise from top-pair plus single top events (here generically indicated as \(tt\), \(W \to \tau \nu \tau \nu\) events and \(Z \to \tau \tau\) events. While the latter comprises final states with two true taus, which are well described in the simulation, the \(W\) and \(t\bar{t}\) background consist of events in which one real tau is correctly reconstructed and the other tau candidates are mis-reconstructed from hadronic activity in the final state. Since mis-identified taus are not well described in the MC, the background contribution from \(tt\) and \(W \to \tau \nu \tau \nu\) is determined simultaneously in a CR defined by inverting the \(m_{\text{eff}}\) cut. Owing to the requirement on \(\Delta\phi\) and of two or more taus, this CR has negligible contamination from multi-jet events. Moreover, a totally negligible contribution is expected in this CR from signal events. The MC overestimates the number of events in the CR compared to data, due to mis-modeling of tau misidentification probabilities. MC studies show that the tau misidentification probability is, to a good approximation, independent of \(m_{\text{eff}}\), so that the measured ratio of the data to MC event yields in the CR can be used to correct the MC background prediction in the SR.

In a similar way, the multi-jet background expectation is computed in a multi-jet dominated CR defined by inverting the \(m_{\text{eff}}\) and \(m_{\text{eff}}\) cuts. In addition, \(E_{T,\text{miss}}^\tau/m_{\text{eff}} < 0.4\) is required to increase the purity of this CR sample. The extrapolated contribution of this background source to the SR is found to be negligible.

7. Systematic uncertainties on the background

The theoretical uncertainty on the MC-based corrected extrapolation of the \(W\) and \(t\bar{t}\) backgrounds from the CR into the SR

\(^3\) The transverse mass \(m_T\) formed by \(E_{T,\text{miss}}^\tau\) and the \(p_T\) of the tau lepton (\(\tau\)) is defined as \(m_T = \sqrt{2p_T E_{T,\text{miss}}^\tau(1 - \cos(\Delta\phi(\tau, p_{T,\text{miss}})))}\).
the $t\bar{t}$ and $W$ backgrounds, these uncertainties are absorbed into the normalisation. The systematic uncertainty associated to pile-up simulation in MC is 1%. The normalisation of the $Z+\text{jets}$ and diboson backgrounds is affected by the uncertainty of 3.7% on the luminosity measurement [55,56]. This results in a 0.8% uncertainty on the total background. The contributions from the different systematic uncertainties result in a total background systematic uncertainty of 41%.

In total $5.3 \pm 1.3 \text{(stat)} \pm 2.2 \text{(sys)}$ background events are expected where the first uncertainty is statistical and includes the statistical component of the background correction factor uncertainty and the second is systematic. Roughly half of the background is composed of $t\bar{t}$ events and the other half is evenly split into $W$ and $Z$ events with accompanying jets.

8. Signal efficiencies and systematic uncertainties

GMSB signal samples were generated on a grid ranging from $\Lambda = 10 \text{ TeV}$ to $\Lambda = 80 \text{ TeV}$ and from $\tan \beta = 2$ to $\tan \beta = 50$. The number of selected events decreases significantly with increasing $\Lambda$ due to the reduced cross section. The cross section drops from 100 pb for $\Lambda = 15 \text{ TeV}$ to 5.0 fb for $\Lambda = 80 \text{ TeV}$. The selection efficiency is highest ($\approx 3\%$) for high $\tan \beta$ and lower $\Lambda$ values, including in the region of the GMSB4030 point ($\Lambda = 40$, $\tan \beta = 30$) which is near the expected limit. It drops to 0.2% in the non-$\tau_1$ NLSP regions and for high $\Lambda$ values. This is primarily a consequence of the light lepton veto and the requirement of two hadronically decaying taus, respectively.

The total systematic uncertainty on the signal selection from the systematic uncertainties discussed in Section 7 ranges between 7.5% and 36% over the GMSB grid. The statistical uncertainty from the limited size of the MC signal samples is of the order of 20%, with variations between 7.6% and 59% at the edges of the accessible signal range. Theory uncertainties related to the GMSB cross section predictions are estimated through variations of the factorisation and renormalisation scales in the NLO PROSPINO calculation between half and twice their default values, by considering variations in $\alpha_s$, and by considering PDF uncertainties using the CTQ6.6M PDF error sets [58]. These uncertainties are calculated for individual SUSY production processes and for each model point, leading to overall theoretical cross section uncertainties between 6.5% and 22%. Altogether this yields $20.8 \pm 3.4 \text{(stat)} \pm 3.6 \text{(sys)} \pm 3.3 \text{(theo)}$ signal events for the GMSB4030 point.

9. Results

Based on the observation of 3 events in the SR and a background expectation of $5.3 \pm 1.3 \text{(stat)} \pm 2.2 \text{(sys)}$ events, an upper limit of 5.9 events from new phenomena, corresponding to an upper limit on the visible cross section of $2.9 \text{ fb}$.

10. Conclusions

A search for events with two or more hadronically decaying tau leptons, large $E_T^{miss}$ and jets is performed using 2 fb$^{-1}$ of $\sqrt{s} = 7 \text{ TeV}$ pp collision data recorded with the ATLAS detector at the LHC. Three events are found, consistent with the expected SM background. The results are used to set a model-independent 95% CL upper limit of 5.9 events from new phenomena, corresponding to an upper limit on the visible cross section of $2.9 \text{ fb}$. Limits on the model parameters are set for a minimal GMSB model. The limit on the SUSY breaking scale $\Lambda$ of $32 \text{ TeV}$ is determined, independent of $\tan \beta$. It increases up to $47 \text{ TeV}$ for $\tan \beta = 37$. These results provide the most stringent tests in a large part of the parameter space considered to date, improving the previous best limits.

Acknowledgements

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

\textsuperscript{u} Also at School of Physics and Engineering, Sun Yat-sen University, Guanzhou, China.
\textsuperscript{v} Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan.
\textsuperscript{w} Also at DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l'Univers), CEA Saclay (Commissariat à l'Energie Atomique), Gif-sur-Yvette, France.
\textsuperscript{x} Also at Section de Physique, Université de Genève, Geneva, Switzerland.
\textsuperscript{y} Also at Departamento de Fisica, Universidad de Minho, Braga, Portugal.
\textsuperscript{z} Also at Department of Physics and Astronomy, University of South Carolina, Columbia, SC, United States.
\textsuperscript{aa} Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary.
\textsuperscript{ab} Also at California Institute of Technology, Pasadena, CA, United States.
\textsuperscript{ac} Also at Institute of Physics, Jagiellonian University, Krakow, Poland.
\textsuperscript{ad} Also at LAL, Univ. Paris-Sud and CNRS/IN2P3, Orsay, France.
\textsuperscript{ae} Also at Laboratory for Particle Physics and Cosmology, Swarthmore College, Swarthmore, PA, United States.
\textsuperscript{af} Also at School of Physics, Shandong University, Shandong, China.
\textsuperscript{ag} Also at CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France.
\textsuperscript{ah} Also at School of Physics and Engineering, Sun Yat-sen University, Guanzhou, China.
\textsuperscript{ai} Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan.
\textsuperscript{aj} Also at DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l'Univers), CEA Saclay (Commissariat à l'Energie Atomique), Gif-sur-Yvette, France.
\textsuperscript{ak} Also at Section de Physique, Université de Genève, Geneva, Switzerland.
\textsuperscript{al} Also at Departamento de Fisica, Universidad de Minho, Braga, Portugal.
\textsuperscript{am} Also at Department of Physics and Astronomy, University of South Carolina, Columbia, SC, United States.
\textsuperscript{an} Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary.
\textsuperscript{ao} Also at California Institute of Technology, Pasadena, CA, United States.
\textsuperscript{ap} Also at Institute of Physics, Jagiellonian University, Krakow, Poland.
\textsuperscript{aq} Also at LAL, Univ. Paris-Sud and CNRS/IN2P3, Orsay, France.
\textsuperscript{ar} Also at Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom.
\textsuperscript{as} Also at Department of Physics, Oxford University, Oxford, United Kingdom.
\textsuperscript{at} Also at Institute of Physics, Academia Sinica, Taipei, Taiwan.
\textsuperscript{au} Also at Department of Physics, The University of Michigan, Ann Arbor, MI, United States.
\textsuperscript{av} Also at Laboratorio de Physique Nucleaire et de Hautes Energies, UPMC and Université Paris-Diderot and CNRS/IN2P3, Paris, France.
\textsuperscript{*} Deceased.
