Search for Pair Production of a New $b'$ Quark that Decays into a $Z$ Boson and a Bottom Quark with the ATLAS Detector

G. Aad et al.*
(Atlas Collaboration)
(Received 5 April 2012; published 16 August 2012)

A search is reported for the pair production of a new quark $b'$ with at least one $b'$ decaying to a $Z$ boson and a bottom quark. The data, corresponding to 2.0 fb$^{-1}$ of integrated luminosity, were collected from $pp$ collisions at $\sqrt{s} = 7$ TeV with the ATLAS detector at the CERN Large Hadron Collider. Using events with a $b$-tagged jet and a $Z$ boson reconstructed from opposite-charge electrons, the mass distribution of large transverse momentum $b'$ candidates is tested for an enhancement. No evidence for a $b'$ signal is detected in the observed mass distribution, resulting in the exclusion at a 95% confidence level of $b'$ quarks with masses $m_{b'} \lesssim 400$ GeV that decay entirely via $b' \rightarrow Z + b$. In the case of a vectorlike singlet $b'$ mixing solely with the third standard model generation, masses $m_{b'} < 358$ GeV are excluded.

The selected events were recorded with a single-electron trigger that is over 95% efficient for reconstructed electrons [18] with momentum transverse to the beam direction, $p_T$, exceeding 25 GeV. At least two opposite-charge electron candidates are required, each satisfying $p_T > 25$ GeV and reconstructed in the pseudorapidity region $|\eta| < 2.47$, excluding the barrel to end-cap calorimeter transition region, $1.37 < |\eta| < 1.52$. In addition, the electron candidates satisfy medium quality requirements [18] on the reconstructed track and properties of the electromagnetic shower. The two opposite-charge electron candidates yielding an invariant mass $m_{ee}$ of the electromagnetic shower. The two opposite-charge electron candidates yielding an invariant mass $m_{ee}$ of the electromagnetic shower. The two opposite-charge electron candidates yielding an invariant mass $m_{ee}$ of the electromagnetic shower. The two opposite-charge electron candidates yielding an invariant mass $m_{ee}$ of the electromagnetic shower. The two opposite-charge electron candidates yielding an invariant mass $m_{ee}$ of the electromagnetic shower. The two opposite-charge electron candidates yielding an invariant mass $m_{ee}$ of the electromagnetic shower.

Jets are reconstructed using the anti-$k_t$ clustering algorithm [19] with a distance parameter of 0.4. The inputs to the algorithm are three-dimensional clusters formed from calorimeter energy deposits. Jets are calibrated using $p_T$- and $\eta$-dependent factors determined from simulation and validated with data [20]. Jets are rejected if they do not satisfy quality criteria to suppress noise and noncollison backgrounds, as are jets whose axis is within $\Delta R = \sqrt{\Delta \eta^2 + \Delta \phi^2} = 0.5$ of a reconstructed electron associated with the $Z$ candidate. A requirement is made to ensure at least 75% of the total $p_T$ of all tracks associated with the jet be attributed to tracks also associated with the selected $pp$ collision vertex [21]. Finally, jets in this analysis are restricted to the region covered by the tracking detectors, $|\eta| < 2.5$, and satisfy $p_T > 25$ GeV. Approximately 81,000 events pass the $Z \rightarrow e^+e^-$ candidate selection and contain at least one selected jet.

The SM production of $Z$ bosons in association with jets accounts for most events passing the $Z+ \geq 1$ jet selection. Two leading-order Monte Carlo (MC) generators, ALPGEN [22] and SHERPA [23], are used to assess the background arising from this process, with ALPGEN providing the baseline prediction. A description of the generation of these samples, in particular, in regard to differences between ALPGEN and SHERPA in the modeling of $Z$ boson production in association with $b$ jets, is detailed in Ref. [24]. The predictions of both are normalized such that the inclusive $Z$ boson cross section used is the HATHOR [29] approximate NNLO value, while MC@NLO values are normalized using single vector boson production NNLO cross sections [25]. The multijet background is estimated using a data sample with both electron candidates passing loose criteria [18] but failing the slightly tighter medium criteria. This sample is normalized to the difference in the inclusive $Z$ sample between the data and all other backgrounds in the region $50 < m_{ee} < 65$ GeV. The small single top, diboson, $Z \rightarrow \tau \tau$, $W \rightarrow e\nu$, and multijet contributions are combined and denoted Other SM.

Figure 1 presents the $e^+e^-$ invariant mass distribution for events passing the $Z+ \geq 1$ jet selection, before imposing the $|m_{ee} - m_Z| < 15$ GeV requirement, together with the SM prediction. The observed and predicted number of events are listed in Table I for this and two other stages of the event selection. Most events passing the $Z+ \geq 1$ jet selection arise from the $Z+ light category. The appreciable lifetime of the $b$ hadron originating from the bottom quark in the decay $b' \rightarrow Z + b$ provides a means to reduce this background source. A $b$ jet tagging algorithm referred to as IP3D + SV1 [32] is utilized to select events with at

![Figure 1](image-url)
least one $b$ jet from the $Z+ \geq 1$ jet sample. The discriminant combines two likelihood variables based on the tracks associated with a jet. The first employs the longitudinal and transverse track impact parameters, while the second utilizes properties of a reconstructed secondary vertex. In a simulated $t\bar{t}$ sample, the requirement on the discriminant defining a $b$ jet is 60% efficient for jets with a $b$ hadron, and yields a light flavor jet rejection rate of 300 [32].

A total of 3466 events satisfy the $Z+ \geq 1$ b jet selection. Figure 2 presents the $e^+e^-$ invariant mass distribution in this sample and the SM prediction, before imposing the $|m_{ee} - m_Z| < 15$ GeV requirement. The accurate modeling of the mass distribution for values beyond the $Z$ boson mass supports the prediction of $t\bar{t}$ and Other SM background events. Within the window around the $Z$ boson mass, ALPGEN and SHERPA agree to within 1% and 7% in the prediction of the number of $Z+\text{light}$ and $Z+\text{charm}$ events, respectively. However, ALPGEN and SHERPA disagree in the prediction of the $Z+\text{bottom}$ contribution, a fact previously reported in an ATLAS cross section measurement of $Z$ bosons produced in association with $b$ jets using a smaller dataset [24]. The ALPGEN and SHERPA $Z+\text{bottom}$ predictions are scaled to account for the difference between data and all other predicted backgrounds in a subsample of the $Z+ \geq 1 b$ jet sample that contains events failing the requirement discussed below on the transverse momentum of the $b^\prime$ candidate. The scale factors are consistent with those measured in Ref. [24], and the invariant mass distribution of secondary vertex tracks is used to confirm the validity of the resulting prediction for the flavor composition in the $Z+ \geq 1 b$ jet sample [24].

Simulated $b^\prime/b^\prime$ events are generated for a range of $b^\prime$ masses using MADGRAPH [33] with the G4LHC extension [6]. PYTHIA [34] performs fragmentation and hadronization of the parton-level events. The signal cross sections are obtained with HATHOR [29], and vary from 80 pb to 30 fb over the range $m_{b^\prime} = 200$–700 GeV. In each sample, one $b^\prime$ decays in the mode $b^\prime \to Z + b$, with the $Z$ boson decaying via $Z \to e^+e^-$. Two separate samples are produced for each mass value, with the other $b^\prime$ decaying either via $b^\prime \to Z + b$ or $b^\prime \to W + t$, and with all decay modes of the $Z$ and $W$ bosons allowed. The factor $\beta = 2 \times \text{BR}(b^\prime \to Zb) - \text{BR}(b^\prime \to Zb)^2$ characterizes the fraction of signal events with at least one $b^\prime \to Z + b$ decay as a function of the branching ratio. The case $\beta = 1$ is equivalent to previous measurements [9] which assumed $\text{BR}(b^\prime \to Zb) = 1$. The case of a vectorlike singlet (VLS) mixing solely with the third SM generation is also considered by computing $\beta$ as a function of the $b^\prime$ mass [5]. Over the range $m_{b^\prime} = 200$–700 GeV, $\beta$ varies from 0.9 to 0.5. A SM Higgs of mass 125 GeV is assumed.

---

**TABLE I.** Number of predicted and observed events at three stages in the event selection. The contributions from SM backgrounds are shown individually, as well as combined into the total SM prediction. The uncertainties on the predicted number of events combine all sources of uncertainty. The number of expected signal events is also listed for two representative $b^\prime$ masses in the case where the branching ratio $\text{BR}(b^\prime \to Zb) = 1$.

The $b'$ candidate is formed from the $e^+ e^-$ pair and the highest $p_T$ $b$ jet. The mass of the $b'$ candidate, $m(Zb)$, is the discriminant distinguishing the background-only and signal-plus-background hypotheses. In $b'$ pair production, the new quarks are typically produced with large transverse momentum, $p_T$. Therefore, a $p_T(Zb) > 150$ GeV requirement is applied to increase the signal sensitivity. Figure 3 presents the $p_T(Zb)$ distribution for data and the predicted SM backgrounds. Additionally, the signal distribution is overlaid for a $b'$ mass of 350 GeV, assuming the VLS scenario value $\beta = 0.63$, and for a mass of 450 GeV, assuming $\beta = 1$.

The fraction of signal events passing all requirements varies from 7% to 43% between $m_{ll} = 200$–700 GeV, assuming $\beta = 1$, with the efficiency to pass the minimum $p_T(Zb)$ requirement contributing most to the degree of variation. The requirement $p_T(Zb) > 150$ GeV was determined by assessing the signal sensitivity for different minimum $p_T(Zb)$ values, as quantified by the expected cross section exclusion limit. The limit is computed using a binned Poisson likelihood ratio test [35] of the $m(Zb)$ distribution for different $m_{ll}$ hypotheses. Pseudoexperiments are generated according to the background-only and signal-plus-background hypotheses, and incorporate the impact of systematic uncertainties. The cross section limit is evaluated using the CL$_s$ modified frequentist approach [35].

The impact of each systematic uncertainty on the normalization and shape of the $m(Zb)$ distribution is assessed for each SM background source and the expected $b'$ signal. The fractional uncertainty on the total number of background events passing the $p_T(Zb) > 150$ GeV requirement is 27%. Significant contributions arise from uncertainties in the $p_T(Zb)$ distribution shape in $Z + \text{jets}$ events. Such sources of uncertainty include the renormalization and factorization scale choice (14%, evaluated using MCFM [36]), shape differences observed between ALPGEN and SHERPA (12%), and variations in the degree of initial and final state QCD radiation (9%). The uncertainty in the efficiency of the $b$-tagging requirement contributes an additional 12%. Other sources of uncertainty contributing at the level of 6% or less include the jet energy scale [20], parton distribution functions (PDF), MC sample sizes, electron identification efficiency, $Z$ boson cross section, luminosity, $b$-jet mistag rate, $t\bar{t}$ cross section, jet energy resolution, trigger efficiency, and the Other SM event yield. Most of the above uncertainties, with the notable exception of the $p_T(Zb)$ modeling uncertainties in $Z + \text{jets}$ events, contribute to the total uncertainty on the signal normalization, which varies between 11% and 14% depending on the $b'$ mass.

Figure 4 presents the $b'$ candidate mass distribution after requiring $p_T(Zb) > 150$ GeV and the predicted SM background. The distributions for the signal scenarios depicted in Fig. 3 are shown overlaid. The data are in agreement with the SM prediction over the full range of $m(Zb)$ values. In the absence of evidence of an enhancement, 95% confidence level (C.L.) cross section exclusion limits are derived. Figure 5 presents the expected and observed cross section limits as a function of $m_{ll}$, computed under the assumption $\beta = 1$. The expected cross section limit was checked to be stable to within 15% over the full mass range considered using the signal samples in which one $b'$ quark
decays via $b' \rightarrow Z + b$ and the other decays via $b' \rightarrow W + t$. The approximate NNLO $b'b'$ cross section prediction is shown multiplied by $\beta = 1$, as well as by the VLS $\beta$ value, with the shaded region representing the total uncertainty arising from PDF uncertainties and the factorization and renormalization scale choice. The prediction is also multiplied by the $\beta$ factors described in the text.

In conclusion, a search with $2.0 \text{ fb}^{-1}$ of ATLAS data is presented for $b'$ quark pair production, with at least one $b'$ decaying to a $Z$ boson and a bottom quark. This decay mode is particularly relevant in the context of vectorlike quarks and is an essential complement to searches in the mode with both $b'$ decaying to a $W$ boson and a top quark. No evidence for a $b'$ is observed in the $Z + b$ jet final state, and new limits are derived on the mass of a $b'$ quark decaying via $b' \rightarrow Z + b$.

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.
