The top quark was discovered in 1995 [1,2] at the Tevatron proton-antiproton collider. The lifetime of the top quark is at least an order of magnitude shorter than the time scale for strong interactions, implying that the top quark decays before hadronization [3–7]. Therefore the spin of the top quark at production is transferred to its decay products and can be measured directly via their angular distributions [4]. While the polarization of $t$ and $\bar{t}$ quarks in a hadronically produced $t\bar{t}$ sample is predicted to be very small, their spins are predicted to be correlated [8–10]. In this Letter the hypothesis that the correlation of the spin of top and antitop quarks in $t\bar{t}$ events is as expected in the standard model (SM), as opposed to the hypothesis that they are uncorrelated, is tested. This tests the precise predictions of $t\bar{t}$ pair production and of top quark decay, which is expected to occur before its spin is flipped by the strong interaction [9–13]. Many scenarios of new physics beyond the SM predict different spin correlations while keeping the $t\bar{t}$ production cross section within experimental and theoretical bounds [14–18]. For example, the spin correlation measured in this Letter may differ from the SM if the $t\bar{t}$ pairs were produced via the exchange of a virtual heavy scalar Higgs boson [19] or if the top quark decayed into a scalar charged Higgs boson and a $b$ quark ($t \rightarrow H^+ b$) [20].

At the LHC $t\bar{t}$ production occurs mostly through the $gg \rightarrow t\bar{t}$ channel. At low $t\bar{t}$ invariant mass it is dominated by the fusion of like-helicity gluon pairs which produce top quarks in the left-left or right-right helicity configurations [13]. When these decay via $t\bar{t} \rightarrow W^+ W^- b\bar{b} \rightarrow t^+ l^- \nu l^- \bar{b} \bar{b}$ they produce charged leptons which possess correlations in azimuthal angle, $\Delta \phi$ [21], in the laboratory frame [13]. In contrast, at the Tevatron production via $q\bar{q}$ annihilation dominates. The different production mechanisms and center-of-mass energies make a measurement of the spin correlation at both colliders complementary [22]. Both the CDF and D0 Collaborations have performed measurements of the spin correlation [23–25], with a recent analysis by the D0 Collaboration reporting evidence for the presence of spin correlation in $t\bar{t}$ events with a significance of 3.1 standard deviations [26].

The azimuthal angle between charged leptons is well measured by the ATLAS detector and does not require reconstruction of the top quarks. Figure 1 shows the distribution of charged lepton $\Delta \phi$ for generated events at parton level for $\sqrt{s} = 7$ TeV, using MC@NLO [27–29] with the CTEQ6.6 parton distribution function (PDF) [30] and a top quark mass of 172.5 GeV. It compares the...
SM prediction (solid line) to a scenario with no spin correlation between top and antitop quarks (dashed line).

Monte Carlo (MC) simulation samples are used to evaluate the contributions, and shapes of distributions of kinematic variables, for signal \( t\bar{t} \) events and background processes not evaluated from complementary data samples. All MC samples are processed with the GEANT4 [36] simulation of the ATLAS detector [37] and are passed through the same analysis chain as data. The simulation includes multiple \( pp \) interactions per bunch crossing (pileup). Events are weighted such that the distribution of the average number of interactions per bunch crossing matches that observed in data. The mean number of pileup interactions varies between 5.7 and 7.1 for the different data-taking periods.

Samples with SM spin correlation and without spin correlation are generated using MC@NLO with the CTEQ6.6 PDF set and a top quark mass of 172.5 GeV. In both cases the events are hadronized using the HERWIG shower model [38,39]. Within the statistical uncertainty of the MC generation the yields of the SM \( t\bar{t} \) and uncorrelated \( \ell\bar{\ell} \) samples are the same. The background MC samples are described in Ref. [40].

Candidate events are selected in the dilepton topology. Channels with \( \tau \) leptons are not explicitly considered, but reconstructed leptons can arise from leptonic \( \tau \) decays and are included in the signal MC samples. The full object and event selection is discussed in Ref. [40]; therefore only a brief overview is given here. The analysis requires events selected online by an inclusive single-lepton trigger (\( e \) or \( \mu \)). The detailed trigger requirements vary throughout data taking, but the \( p_T \) threshold ensures that the triggered lepton candidate is in the efficiency plateau. Electron candidates are reconstructed using energy deposits in the EM calorimeter associated to reconstructed tracks of charged particles in the ID. Muon candidate reconstruction makes use of tracking in the MS and ID. Jets are reconstructed with the anti-\( k_t \) algorithm [41] with a radius parameter \( R = 0.4 \), starting from energy clusters of adjacent calorimeter cells. The symbol \( E_T^{\text{miss}} \) is used to denote the magnitude of the missing transverse momentum [42]. The following kinematic requirements are made:

(i) Electron candidates are required to have \( p_T > 25 \text{ GeV} \) and \( |\eta| < 2.47 \), excluding electrons from the transition region between the barrel and end-cap calorimeters defined by \( 1.37 < |\eta| < 1.52 \). Muon candidates are required to have \( p_T > 20 \text{ GeV} \) and \( |\eta| < 2.5 \). Events must have exactly two oppositely-charged lepton candidates \( e^+e^-, \mu^+\mu^-, e^+e^- \).

(ii) Events must have at least two jets with \( p_T > 25 \text{ GeV} \) and \( |\eta| < 2.5 \).

(iii) Events in the \( e^+e^- \) and \( \mu^+\mu^- \) channels are required to have \( m_{\ell\ell} > 15 \text{ GeV} \) to ensure compatibility with the MC samples and remove contributions from \( Y \) and \( J/\psi \) production.

(iv) Events in the \( e^+e^- \) and \( \mu^+\mu^- \) channels must satisfy \( E_T^{\text{miss}} > 60 \text{ GeV} \) to suppress backgrounds from

\[
A = \frac{N(||) + N(||) - N(\|) - N(\|)}{N(||) + N(||) + N(\|) + N(\|)}.
\]
Z/γ + jets and W + jets events. In addition, \( m_\ell \ell \) must differ by at least 10 GeV from the Z-boson mass (\( m_Z = 91 \) GeV) to further suppress the Z/γ + jets background.

(v) For the e±μ± channel, no \( E_\text{miss} \) or \( m_\ell \ell \) cuts are applied. In this case, the remaining background from Z/γ(→ ττ) + jets production is further suppressed by requiring that the scalar sum of the \( p_\text{T} \) of all selected jets and leptons is greater than 130 GeV.

The event selection rejects Z/γ + jets events with low invariant mass and those with invariant mass near the Z-boson mass. However, Z/γ + jets events with an \( e^+e^- \) or \( μ^+μ^- \) invariant mass outside of these regions can enter the signal sample when there is large \( E_\text{miss} \), typically from mismeasurement. These events are difficult to properly model in simulations due to uncertainties on the non-Gaussian tails of the \( E_\text{miss} \) distribution, on the cross section for Z-boson production with multiple jets, and on the lepton energy resolution. The Z/γ + jets background in dielectron and dimuon events is evaluated using a data-driven (DD) technique in which the MC simulation yield of Z/γ + jets events is normalized to the data using a control region defined by a dilepton invariant mass within 10 GeV of the Z-boson mass [40].

The backgrounds from events with misidentified (fake) leptons, primarily from W + jets events, are evaluated from data using a matrix method [43]. The matrix method makes use of the efficiency of real lepton identification and rate of lepton misidentification measured in several control regions, which are chosen to be enhanced in different sources of fake leptons [40]. Contributions from real leptons due to W + jets events in the fake lepton control region are subtracted using MC simulation. Comparisons of data and MC simulation in control regions are used to tune the rates to the expected signal region composition. The fake lepton yield is then estimated by weighting each event in a sample containing one or two loosely identified leptons.

The contributions from other electroweak background processes with two real leptons, such as single top, Z → ττ, WW, ZZ, and WZ production are determined from MC simulations normalized to the theoretical predictions. The expected numbers of signal and background events are compared to data in Table I. The number of observed events in each channel is: 477 for the \( e^+e^- \) channel, 906 for the \( μ^+μ^- \) channel, and 2930 for the \( e^±μ^± \) channel, which dominates the total yield due to the looser selection criteria.

A binned log-likelihood fit is used to extract the spin correlation from the \( Δφ \) distribution in data. The fit includes a linear superposition of the distribution from SM \( t\bar{t} \) MC simulation with coefficient \( f_{SM} \), and from the uncorrelated \( t\bar{t} \) MC simulation with coefficient (1 − \( f_{SM} \)). The \( e^+e^- \), \( μ^+μ^- \), and \( e^±μ^± \) channels are fitted simultaneously with a common value of \( f_{SM} \), a \( t\bar{t} \) normalization that is allowed to vary (per channel) and a fixed background normalization. The fitted \( t\bar{t} \) normalizations are in agreement with the theoretical prediction of the production cross section [44]. Negative values of \( f_{SM} \) correspond to an anticorrelation of the top and antitop quark spins. A value of \( f_{SM} = 0 \) implies that the spins are uncorrelated and values of \( f_{SM} > 1 \) indicate a larger strength of the \( t\bar{t} \) spin correlation than predicted by the SM. The extraction of \( f_{SM} \) using the fitting procedure has been verified over a wide range of possible values, \( -1 \leq f_{SM} \leq 2 \), using MC simulation pseudoexperiments with full detector simulation.

Figure 2 shows the reconstructed \( Δφ \) distribution for the sum of the three dilepton channels in data. SM and uncorrelated \( t\bar{t} \) MC samples are overlaid along with the expected backgrounds.

Systematic uncertainties are evaluated by applying the fit procedure to pseudoexperiments created from MC samples modified to reflect the systematic variations. The fit of \( f_{SM} \) is repeated to determine the effect of each

**FIG. 2** (color online). Reconstructed charged lepton \( Δφ \) distribution for the sum of the three dilepton channels. The integrated number of events for both the SM and the uncorrelated \( t\bar{t} \) samples is fixed to the value from the fit. MC background samples are normalized using their predicted cross sections and the DD method in the case of Z/γ + jets. The fake lepton background is evaluated from data.
systematic uncertainty using the nominal templates. The difference between the means of Gaussian fits to the results from many pseudexperiments using nominal and modified pseudodata is taken as the systematic uncertainty on $f^{\text{SM}}$.

The effect of the luminosity uncertainty is evaluated by scaling the number of signal and background events by the luminosity uncertainty, for backgrounds evaluated from MC simulation. Because of the finite size of the MC samples, the signal and background templates have statistical uncertainties. Each template bin is varied within its uncertainty, then $f^{\text{SM}}$ is reevaluated. The resulting distribution for $f^{\text{SM}}$ is fitted with a Gaussian. The width is taken as the MC simulation statistical uncertainty.

The mismodeling of the muon (electron) trigger, reconstruction, and selection efficiencies in the simulation is corrected using scale factors derived from measurements of the efficiency in data. $Z \rightarrow \mu^+ \mu^-$ ($Z \rightarrow e^+ e^-$) decays are used to obtain scale factors as a function of the kinematic variables of the leptons. Systematic uncertainties on these scale factors are evaluated by varying the selection of events used in the efficiency measurements and by checking the stability of the measurements over the course of the data-taking period. The modeling of the lepton momentum scale and resolution is studied using the reconstructed dilepton invariant mass distributions of $Z/\gamma^*$ candidate events and the simulation is adjusted accordingly.

The jet energy scale, jet energy resolution, and reconstruction efficiency affect the acceptance. The jet energy scale and its uncertainty are derived by combining information from test-beam data, LHC collision data and simulation [45]. For jets within the acceptance, the jet energy scale varies in the range 4%–10% as a function of jet $p_T$ and $\eta$, including an additional uncertainty due to multiple $pp$ interactions. The energy resolution for jets is measured in dijet events and agrees with predictions from simulation [46–48] interfaced to HERWIG. To estimate the uncertainty due to the parton shower modeling and fragmentation, the difference between POWHEG interfaced to HERWIG (cluster fragmentation) and PYTHIA [49] (string fragmentation) is taken. The uncertainty due to ISR/FSR is evaluated using the ACERMC generator [50] interfaced to the PYTHIA shower model, by varying the parameters controlling ISR and FSR in a range consistent with those used in the Perugia Hard/Soft tune variations [51]. The average of the absolute values of the upward and downward variations is taken as the systematic uncertainty. The impact of the choice of PDF in simulation was studied by reweighting the MC samples to three PDF sets (CTEQ6.6, MSTW2008NLO [52], and NNPDF20 [53]) and taking the largest of either the variation interval (from the error sets) or difference between the central values of any two PDF sets [32]. The systematic uncertainty associated with the top quark mass is assessed using MC@NLO samples generated assuming different top quark masses in the range 167.5 to 177.5 GeV in increments of 2.5 GeV. The values of $f^{\text{SM}}$ are fitted as a linear function of the top quark mass and a conservative systematic uncertainty is obtained by evaluating this function at 172.5 ± 2.5 GeV.

Overall normalization uncertainties on the backgrounds from single top quark and diboson production are taken to be 10% [54,55] and 5% [56], respectively. The resulting uncertainty on $f^{\text{SM}}$ is found to be negligible. The systematic uncertainties from the background evaluations derived from the data include the statistical uncertainties in these methods as well as the systematic uncertainties arising from lepton and jet identification and reconstruction, and the MC simulation estimates used. An uncertainty on the DD $Z/\gamma^* +$ jets estimation is evaluated by varying the $E_T^{\text{miss}}$ cut in the control region by ±5 GeV and is found to be negligible. A mismodeling of the Z-boson $p_T$ is observed in the Z-boson dominated control region. The Z-boson $p_T$ distribution is weighted to achieve agreement with data and the difference between the unweighted and weighted MC simulation is taken as an additional, but negligible, modeling uncertainty on $f^{\text{SM}}$. For the DD fake lepton background the systematic uncertainty affects the shape of the $\Delta \phi$ distribution. Systematic uncertainties are derived by adjusting the signal region composition based on uncertainties estimated from MC simulation, and by comparing data and MC samples. The different sources of fake leptons have different shapes and the change in relative flavor composition of the sample gives an estimate of the shape uncertainty.

Because of a hardware failure a small rectangular region of the LAr calorimeter could not be read out in a subset of the data (0.87 fb$^{-1}$). This affects the electron, jet, and $E_T^{\text{miss}}$ reconstruction. Electrons within the affected region are rejected, as are events in which a jet with $p_T > 20$ GeV is in the affected region. The MC simulation is divided into subsamples based on the fraction of the total luminosity affected and treated in the same way as data. A systematic uncertainty is evaluated by comparing MC simulation with and without the jet and electron rejection.
TABLE II. Summary of the effect of statistical and systematic uncertainties on the measured value of $f^\text{SM}$ for the combined fit.

The effect of the systematic uncertainties in terms of $\Delta f^\text{SM}$ are listed in Table II. The total systematic uncertainty is calculated by combining all systematic uncertainties in quadrature.

The measured value of $f^\text{SM}$ for the combined fit is found to be $1.30 \pm 0.14\text{(stat)}^{+0.27}_{-0.22}\text{(syst)}$. This can be used to obtain a value for $A^\text{measured}$ using $A^\text{measured} = A^\text{SM}_{\text{basis}} \cdot f^\text{SM}$, where the subscript “basis” indicates a chosen spin basis [11]. For the helicity basis this results in $A^\text{helicity} = 0.40 \pm 0.04\text{(stat)}^{+0.05}_{-0.06}\text{(syst)}$, and for the maximal basis $A^\text{maximal} = 0.57 \pm 0.06\text{(stat)}^{+0.12}_{-0.10}\text{(syst)}$, where the SM predictions are 0.31 and 0.44, respectively. MC simulation pseudoexperiments including systematic uncertainties are used to calculate the probability that a value of $f^\text{SM}$ or larger is measured using the assumption of $f^\text{SM} = 0$. For the observed limit the value of $f^\text{SM}$ measured in data is used and for the expected limit a value of $f^\text{SM} = 1$ is used. The hypothesis of zero $t\bar{t}$ spin correlation is excluded with a significance of 5.1 standard deviations. The expected significance is 4.2 standard deviations.

In conclusion, the first measurement of $t\bar{t}$ spin correlation at the LHC has been presented using 2.1 fb$^{-1}$ of ATLAS data in the dilepton decay topology. A template fit is performed to the $\Delta \phi$ distribution and the measured value of $f^\text{SM} = 1.30 \pm 0.14\text{(stat)}^{+0.27}_{-0.22}\text{(syst)}$ is consistent with the SM prediction. The data are inconsistent with the hypothesis of zero spin correlation with a significance of 5.1 standard deviations.

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently. We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC, and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST, and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR, and VSC CR, Czech Republic; DNRF, DSNRC, and Lundbeck Foundation, Denmark; EPLANET and ERC, European Union; IN2P3-CNRS, CEA-DSM/IRFU, France; GNAS, Georgia; BMBF, DFG, HGF, MPG, and AvH Foundation, Germany; GSRT, Greece; ISF, MINERVA, GIF, DIP, and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; FOM and NWO, The Netherlands; RCN, Norway; M NiSW, Poland; GRICES and FCT, Portugal; MERSYS (MECTS), Romania; MES of Russia and ROSATOM, Russian Federation; JINR, MSTD, Serbia; MSSR, Slovakia; ARRS and MVZT, Slovenia; DST/NRF, South Africa; MICINN, Spain; SRC and Wallenberg Foundation, Sweden; SER, SNSF and Cantons of Bern and Geneva, Switzerland; NSC, Taiwan; TAEK, Turkey; STFC, the Royal Society and Leverhulme Trust, United Kingdom; DOE and NSF, United States of America. The crucial computing support from all WLCG partners is acknowledged gratefully, in particular, from CERN and the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INFN-CNAF (Italy), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (U.K.) and BNL (U.S.) and in the Tier-2 facilities worldwide.

The ATLAS coordinate system is right-handed with the pseudorapidity $\eta$ defined as $\eta = -\ln \tan(\theta/2)$, where the polar angle $\theta$ is measured with respect to the LHC beam line. The azimuthal angle $\phi$ is measured with respect to the $x$ axis, which points towards the center of the LHC ring. The $z$ axis is parallel to the anticlockwise beam viewed from above. Transverse momentum and energy are defined as $p_T = p \sin \theta$ and $E_T = E \sin \theta$, respectively.

National Scientific and Educational Centre for Particle and High Energy Physics, Minsk, Republic of Belarus
Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts, USA
Group of Particle Physics, University of Montreal, Montreal, Quebec, Canada
P.N. Lebedev Institute of Physics, Academy of Sciences, Moscow, Russia
Institute for Theoretical and Experimental Physics (ITEP), Moscow, Russia
Moscow Engineering and Physics Institute (MEPhI), Moscow, Russia
Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
Fakultät für Physik, Ludwig-Maximilians-Universität München, München, Germany
Max-Planck-Institut für Physik (Werner-Heisenberg-Institut), München, Germany
Nagasaki Institute of Applied Science, Nagasaki, Japan
Graduate School of Science, Nagoya University, Nagoya, Japan
INFN Sezione di Napoli, Napoli, Italy
Dipartimento di Fisica, Università di Napoli, Napoli, Italy
Department of Physics and Astronomy, University of New Mexico, Albuquerque, New Mexico, USA
Institute for Mathematics, Astrophysics and Particle Physics, Radboud University Nijmegen/Nikhef, Nijmegen, The Netherlands
Nikhef National Institute for Subatomic Physics and University of Amsterdam, Amsterdam, The Netherlands
Department of Physics, Northern Illinois University, DeKalb, Illinois, USA
Budker Institute of Nuclear Physics, SB RAS, Novosibirsk, Russia
Department of Physics, New York University, New York, New York, USA
The Ohio State University, Columbus, Ohio, USA
Faculty of Science, Okayama University, Okayama, Japan
Homer L. Dodge Department of Physics and Astronomy, University of Oklahoma, Norman, Oklahoma, USA
Department of Physics, Oklahoma State University, Stillwater, Oklahoma, USA
Palacký University, RCPTM, Olomouc, Czech Republic
Center for High Energy Physics, University of Oregon, Eugene, Oregon, USA
LAL, Université Paris-Sud and CNRS/IN2P3, Orsay, France
Graduate School of Science, Osaka University, Osaka, Japan
Department of Physics, University of Oslo, Oslo, Norway
Department of Physics, Oxford University, Oxford, United Kingdom
INFN Sezione di Pavia, Pavia, Italy
Dipartimento di Fisica, Università di Pavia, Pavia, Italy
Department of Physics, University of Pennsylvania, Philadelphia, Pennsylvania, USA
Petersburg Nuclear Physics Institute, Gatchina, Russia
INFN Sezione di Pisa, Pisa, Italy
Dipartimento di Fisica E. Fermi, Università di Pisa, Pisa, Italy
Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, Pennsylvania, USA
Laboratorio de Instrumentacao e Fisica Experimental de Particulas - LIP, Lisboa, Portugal
Departamento de Fisica Teorica y del Cosmos and CAFPE, Universidad de Granada, Granada, Spain
Institute of Physics, Academy of Sciences of the Czech Republic, Praha, Czech Republic
Faculty of Mathematics and Physics, Charles University in Prague, Praha, Czech Republic
Czech Technical University in Prague, Praha, Czech Republic
State Research Center Institute for High Energy Physics, Protvino, Russia
Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom
Physics Department, University of Regina, Regina, Saskatchewan, Canada
Ritsumeikan University, Kusatsu, Shiga, Japan
INFN Sezione di Roma I, Roma, Italy
Dipartimento di Fisica, Università La Sapienza, Roma, Italy
INFN Sezione di Roma Tor Vergata, Roma, Italy
Dipartimento di Fisica, Università di Roma Tor Vergata, Roma, Italy
INFN Sezione di Roma Tre, Roma, Italy
Also at Faculdade de Ciencias and CFNUL, Universidade de Lisboa, Lisboa, Portugal.
Also at Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom.
Also at TRIUMF, Vancouver, BC, Canada.
Also at Department of Physics, California State University, Fresno, CA, USA.
Also at Novosibirsk State University, Novosibirsk, Russia.
Also at Fermilab, Batavia, IL, USA.
Also at Department of Physics, University of Coimbra, Coimbra, Portugal.
Also at Università di Napoli Parthenope, Napoli, Italy.
Also at Institute of Particle Physics (IPP), Canada.
Also at Department of Physics, Middle East Technical University, Ankara, Turkey.
Also at Louisiana Tech University, Ruston, LA, USA.
Also at Department of Physics and Astronomy, University College London, London, United Kingdom.
Also at Group of Particle Physics, University of Montreal, Montreal, QC, Canada.
Also at Department of Physics, University of Cape Town, Cape Town, South Africa.
Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan.
Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany.
Also at School of Physics, Shandong University, Shandong, China.
Also at CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France.
Also at School of Physics and Engineering, Sun Yat-sen University, Guanzhou, China.
Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan.
Also at DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l’Univers), CEA Saclay (Commissariat a l’Energie Atomique), Gif-sur-Yvette, France.
Also at Section de Physique, Université de Genève, Geneva, Switzerland.
Also at Departamento de Física, Universidade de Minho, Braga, Portugal.
Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary.
Also at California Institute of Technology, Pasadena, CA, USA.
Also at Institute of Physics, Jagiellonian University, Krakow, Poland.
Also at LAL, Univ. Paris-Sud and CNRS/IN2P3, Orsay, France.
Also at Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom.
Also at Institute of Physics, Academia Sinica, Taipei, Taiwan.
Also at Department of Physics, The University of Michigan, Ann Arbor, MI, USA.
Also at Laboratoire de Physique Nucléaire et de Hautes Energies, UPMC and Université Paris-Diderot and CNRS/IN2P3, Paris, France.
