The RoboCup Rescue as training ground

Arnoud Visser

Context

- After the Great Hanshin Earthquake of 1995 in Kobe, the Japanese government decided to promote research related to the problems encountered during large-scale urban disasters.
- A major outcome of this initiative was the RoboCup Rescue competitions. This lead to both versatile robots as control software for large teams of rescue agents.

Challenge

- After a disaster a team of robots, must explore the devastated city. Ambulances have to find as many victims as possible, dig them out and bring them to a hospital. Fire fighters have extinguish fires before the situation goes out of hand. Police can help to patrol and explore, but can also clear the road for the other agents.

Learning Coordination Policies

The coordination problem is described as a dec-POMDP, which is interpreted as a series of Bayesian games. In this Bayesian game each robot has some private information (not communicated with the team). This private information is clustered into a type of observation histories. This Bayesian game is used to find a joint policy designed to maximize the average result achieved on all joint action-observation histories.

Results

To apply Bayesian games to realistic RoboCup Rescue scenario’s, the decision making is decomposed into a high-level Bayesian game and low-level MDP:

Conclusion

Bayesian Game approximations make it possible to bridge the gap to coordination problems encountered in benchmarks as the RoboCup Rescue. Modeling that each robot has a certain amount of private information, next to a certain amount of common knowledge, is a natural assumption. Also online planning is natural in such dynamic situations.
