Chapter 4: Pathway to political participation.: The influence of online and offline news media on internal efficacy and turnout of first time voters

Manuscript accepted to be published in American Behavioral Scientist

Abstract
News media play a key role in informing young citizens about politics and cultivating a sense of political efficacy. Online news media, in particular, are expected to have a positive impact due to their interactivity and new opportunities to share and discuss information. This study analyzes the impact of online and offline news media use on the growth in internal efficacy among adolescents, based on data collected in a three wave panel survey in the Netherlands (N=729). Additionally the impact of internal efficacy on turnout is being tested using a fourth wave of the same sample (N=612). The results show that while newspaper reading has the strongest effects among traditional news sources, actively participating in the communication process of political information online has the strongest impact on internal efficacy. Internal efficacy, in turn, is found to be a significant predictor of first time voters. The chapter concludes with a discussion of media use as a pathway to political participation through internal political efficacy.
To many teenagers and adolescents the political world appears to be a very complicated place. So complicated, in fact, that they have the impression that they are not qualified or competent enough to participate in it. The decrease of internal political efficacy among the youngest generation is often seen as a serious threat for democracy (Kaid, McKinney, & Tedesco, 2007). Social scientists have therefore devoted a considerable amount of work to gain insight into how adolescents can learn about politics (see also Chapter 3 of this dissertation) in order to feel competent enough to turn out and vote (Beaumont, 2010; Delli Carpini, 2000).

In the discussion about potential solutions to the problem, media, in particular new media, play a key role as they can provide relevant information about political actors and processes and foster to the political understanding of their users. After all, citizens of the youngest generation are the first digital natives and have ample skills to search, read, react to, and create political messages on the Internet. Moreover, in many European countries access to the Internet for this generation is almost universal. In the Netherlands, for example, 95% of 15 to 25 year olds use the Internet on a daily basis (CBS).

There is some empirical evidence that indicates that internet use, internal political efficacy, political participation, and turnout of adolescents are indeed connected (Kushin & Yamamoto, 2010; Quintelier & Vissers, 2008). However, most of these studies are based on cross-sectional data or small scale experimental research. This chapter adds to the existing research in two ways. First, by relying on panel survey data collected over the course of two years the level of internal efficacy is not investigated at a fixed point in time. The focus is on change in the dependent variable over time and its potential causes. This way, this study answers a recent call for a longitudinal perspective on the phenomenon (Weaver Lariscy, Tinkham, & Sweetser, 2011).

Second, I do not look at the Internet as an isolated source of information. Instead this study includes classic information sources, such as newspapers and TV news as well as new media sources of information to find out which of these sources contribute to the development of internal efficacy. By providing an integrated analytical model of a typical political information diet of an adolescent
and its effect on internal political efficacy, this chapter also contributes to the academic debate on sources of political efficacy in a theoretical way. Finally, evidence is provided that internal political efficacy has a strong impact on electoral participation in the same sample, arriving at a comprehensive analysis of the pathway from adolescent news media use to political participation.

**Digital natives and internal political efficacy**

political efficacy is at the core of beliefs and values needed to participate in a democratic society. It is a personality trait acquired early in life that influences the degree to which citizens participate in politics throughout their lives. Therefore, determinants and mechanisms leading to the development of “the feeling that political and social change is possible, and that the individual citizen can play a part in bringing about the change” (Campbell, Gurin, & Miller, 1971, p. 187) have been in the focus of research for the past sixty years in political science and psychology alike (Beaumont, 2010). Two dimensions of the concept can be distinguished: external efficacy, which primarily deals with the “responsiveness of governmental authorities and institutions to citizens’ demands” (Niemi, Craig, & Mattei, 1991, p. 1408) and internal efficacy, defined as beliefs about one’s own “competence to understand and to participate effectively in politics” (Niemi et al., 1991, p. 1408). Closely related to the latter dimension is information efficacy, a concept put forward by Kaid and colleagues (2007) describing voters confidence in their own political knowledge.

Mass media, in particular newspapers, have been found to play an important role in the development of political efficacy among young citizens in the past (Chaffee & Kanihan, 1997). By watching news on TV and reading about the political world in daily newspapers adolescents familiarize themselves with political actors and processes and build political knowledge (Delli Carpini, 2000; Shah, McLeod, & Lee, 2009). Over the course of years they become increasingly confident about their skills to participate in politics and reach sufficient levels of political efficacy.
However, political information in the mass media does not reach a large share of the youngest cohort anymore. According to some scholars, declining numbers in newspaper readership among young readers, decreasing interest in TV news (Huang, 2009) and dramatic gaps in political knowledge (Kaid et al., 2007) are all symptoms of the same disease. The youngest generation – in the words of Mindich (2005) – is “tuned out” from the traditional news. Others argue that adolescents have not tuned out but found a new arena of political information: the Internet. This is not simply a shift of information source, political information on the Internet can be a completely different experience due to its social (Bennett, 2008) and interactive (Tedesco, 2007) quality. To the youngest generation, that is familiar with the social character of information on the Internet, a news item is more than an event shown on the media, it something that can be shared, forwarded, commented on or remixed (Coleman, 2008).

In the context of explaining growth in internal political efficacy this is an important notion. Previous studies have shown that talking about political events is a much better predictor on outcome variables of political involvement than mere exposure to the news (Shah et al., 2009). This is due to the way adolescents process political information. During conversations about abstract political processes with peers, parents or teachers, they make sense of what happened and are introduced to potential interpretations of the events (Mutz, 2002). Of course, events reported in traditional news media can spark political discussions as well, but on the Internet a political debate is more accessible. Articles usually allow readers to comment and engage in a debate with other readers, they can be shared on SNS with minimal effort, and hyperlinks provide the opportunity to find out more about the subject or even participate online, for example by signing an online petition. Moreover, conversations can be started without the need to be at the same place at the same time. Finally, to the youngest cohort that spends a significant share of the day on social media, sharing and talking online about something they have encountered is a standard way to deal with information (Weaver Lariscy et al., 2011).
However, despite growing empirical support for the causal mechanism connecting use of online political information and internal efficacy (Bakker & de Vreese, 2011; Lee, Shah, & McLeod, 2012; Tedesco, 2007) positive effects on adolescents are still hard to trace on a large scale in the field (Boulianne, 2009; Esser & de Vreese, 2007). If effects of political communication are found, other sources of information like newspapers and TV were omitted from the model and the effects are rather small (e.g. Kenski & Stroud, 2006). This might be a consequence of limited interest in political online participatory media among adolescents (Bakker, 2013) and the countless opportunities to select information that is welcome and even personalize news sources in a way to avoid unwanted (political) news.

Hypotheses and analytical model

In order to study effects of news media on internal political efficacy and participation it is important to take into account all aspects relevant to the process. An integrated model should include measures of usage of traditional sources of political information, TV news and newspapers, as well as online sources of political information.

H1: News use has a positive effect on internal efficacy.
H1a: Use of TV news has a positive effect on internal efficacy.
H1b: Use of newspapers a positive effect on internal efficacy.
H1c: Use of online news sources has a positive effect on internal efficacy.

Moreover, we need to not merely include a measure of internet usage, but differentiate what it means: simply reading an article or actively engaging in a political discussion by forwarding or commenting on it (civic messaging) (see also Bakker & de Vreese, 2011). In the latter case a much stronger effect is to be expected as the communicative process inspires information processing and taking a stance on political issues thereby empowering young citizens (Tedesco, 2007). According to the communication mediation model by Shah et al. (2005), these effects could even fully mediate effects of online political information sources.

H2: Civic messaging has a positive effect on internal efficacy.
Internal efficacy as a driver of political participation

A decrease in electoral political participation among the youngest generation has raised concerns both in the scientific and political world. Though the US have witnessed a recent increase in turnout among the youngest voters, the general trend is towards less and less participation. In Europe the last few elections were characterized by an increasing abstinence of young citizens from the ballots. In the Netherlands the turnout rate among voters younger than 25 has dropped by over 20% in the last three elections (CBS).

According to the research of Kaid and colleagues (2007) this can be deducted to a lack of internal political efficacy, or information efficacy. Especially the youngest generation feels that they lack the competence and knowledge to take an electoral decision. Given that internal efficacy is highly predictive of political participation among adults as well (Clarke & Acock, 1989; Scheufele & Nisbet, 2002), I expect to find that those who feel confident about their political knowledge and understanding are more inclined to turnout at the first elections they are eligible to participate.

H3: Internal efficacy has a positive influence on the likelihood to turn out at the first elections.

Method

In order to investigate the influence of differential media use on internal efficacy, I rely on a three wave panel survey conducted in the Netherlands between 2010 and 2012 among a sample of adolescents aged 15 to 18 at the beginning of the survey. To test the effect of internal efficacy a fourth wave was added directly following the general election taking place in the Netherlands in October 2012.

The data collection was funded in part by the Amsterdam School of Communication Research and in part by the Swiss Science Foundation within the framework of NCCR democracy.
Sample

The sample was drawn from a population representative database administered by a Dutch opinion poll institute, GfK, using a light quota sample. The quotas used were age (15 to 18), gender, and education. 1653 respondents participated in the first wave (June 16th through July 10th 2010). 1186 of those respondents also participated in the second wave taking place from June 16th through July 10th 2011 (attrition rate: 28%). The third wave took place from June 14th to July 3rd 2012. 888 respondents participated in the third wave (attrition rate: 25%).

The fourth measurement took place from September 14th to September 24th 2010. 746 respondents participated in the final wave (attrition rate: 16%). Panel attrition did not lead to a significant change in the composition of the panel with regard to key demographic variables age, gender, and education.

Measures

News use: Three different modes of news use are included in the model explaining internal efficacy: TV news use, newspaper use, and internet news sources. All items concerning news use are measured as exposure to a specific news outlet in days a week (1 to 7). To achieve a parsimonious model, measures of use of specific news outlets are combined by calculating the mean per mode of news. For TV news use I combined use scores of the main evening news broadcast in public and commercial TV (M: 3.49, SD: .03). Internet news use is a combined measure of use of a webpage of a newspaper, webpage of a TV news show, and use of the main online only news source in the Netherlands nu.nl (M:2.54, SD:.03). Newspaper use was assessed by combining exposure scores to national quality newspapers and regional newspapers (M: 2.25, SD: .03).

Civic messaging: The level of civic messaging was assessed using a scale of items measuring participation in any of the following forms of political online communication (M: 0.18, SD: 004): Post a political message or video on a social network site (SNS), chat or (micro)blog about politics, sign an online petition, participate in an online discussion, start an online discussion about politics, organize an online petition, join a political cause on a SNS, forward an email with
political content, and email an politician. All items were measured on a three point scale (never, sometimes, often) (Cronbach’s Alpha: .80). A factor analysis was carried out to insure that the scale is one-dimensional.

**Internal efficacy:** Internal efficacy was measured using the standard item: “Sometimes politics seem so complicated that a person like me can’t really understand what’s going on”. It has been a standard item in the internal efficacy scales used in the American National Election for decades (Niemi et al., 1991) and is also used as a single item indicator in large scale surveys like the European Social Survey or the Norwegian election study. The item was measured on a seven point scale (M: 3.41, SD: .03).

**Turnout:** Turnout at the first elections is assessed as a binary measure of self-reported behavior. In order to decrease over-reporting of turnout the questionnaire offered three different categories to report non-participation (“normally I am voting, but this time I could not make it”; “I thought about voting, but this time I did not do it”, and “I have not voted”) which were later recoded into one category.

**Controls:** Age, gender, and formal education were added to the model as control variables. Education is measured by type of school that the respondent is currently attending or has attended in the past (low, middle, or high).

**Analysis**
To make optimal use of the panel data random effects generalized least square estimation is used, because it is the most efficient form estimation and provides the opportunity to control for relevant background factors. To insure the reliability of the analysis a Hausman test was carried out that yielded no significant differences between fixed and random effects model (p>.01). The advantage of this approach is that instead of predicting a level of internal efficacy at a given point in time, as a cross sectional or auto-regressive model would, this model predicts change in the dependent variable based on change in the independent variables (for example, if adolescents start reading a daily newspaper, or starts engaging in online
This means that the causal relationships are tested in a more valid and conservative way.

However, this approach forecloses to test a full model including media use, internal efficacy and turnout, as the latter variable is only measured once. The analysis is therefore split in a panel model predicting change in internal efficacy and a model that predicts turnout with internal efficacy as the main predictor. Moreover, measures of news use were not included in the final wave of the panel, as the final wave of the survey had to be rather short in length. I therefore test the effect of internal efficacy on turnout using a minimal, parsimonious model. To ensure reliability of the results the model is retested including an inclusive set of known factors of internal efficacy that have been measured during the third wave, three months prior to the elections.

Results

Table 4.1 presents the results of the panel data regression analysis explaining change in internal political efficacy. The first model includes the use of the three kinds of news sources: TV news, online news, and newspapers as well as control variables. When comparing the three modes of news use it becomes apparent that newspaper usage is the strongest and most significant predictor of internal political efficacy. TV news use has no significant impact on the dependent variable, whereas the usage of online news sources is predicted to have a slightly significant effect on internal political efficacy. Hence, H1 is partially confirmed by the analysis. Both online and offline news media contribute to rising levels of internal efficacy, with the exception of TV news.

However, this effect becomes insignificant once civic messaging is added to the model (Model 2), implying that active online political communication mediates the effect of political information obtained online. Looking at the second model it also becomes clear that civic messaging is by far the most important predictor in explaining an increase in internal political efficacy over time. The analysis therefore supports the proposition of H2.
Turning to the effect of internal efficacy on the likelihood to participate in the first elections I find strong support for H3 in my data (Table 4.2). As it becomes apparent from Table 4.2 internal efficacies is a key driver of turnout. If young voters feel only a little more efficacious, measured in one item step on a seven point scale, the odds to turn out and vote increases by nearly 50%.

Given the small N, we chose to present a parsimonious model including only a few key control variables here. A model based on an inclusive list of control variables (political interest, social economic status, parental education, mobilization through others, and general media use was also estimated and yielded no different results with regard to significance level and size of the effect. These control variables were measured during the third wave three months prior to the elections.

Discussion

In this chapter I analyzed how news use and civic messaging can contribute to the growth of internal efficacy in a period that is crucial for the development of political skills, namely the two years leading up to the first general election. The effects of the different news sources are not tested in a vacuum, but in an integrated model of political communication relevant to the age group. This allows comparing the influence of the different sources and reliably attributing effects to the correct source.

The results show that for young citizens acquiring confidence in their competence to participate in the political system by using political information is a complex process. Whether or not news use contributes to internal political efficacy depends a) on the type of medium in which political information is presented and b) on the level of involvement. According to the data, newspaper reading is still the most effective information source with regard to the development of internal political efficacy. These results are in line with research dating back as far as the 1970s as well as recent studies on the effect of news use on political knowledge and engagement (Chaffee & Kanihan, 1997; Esser & de Vreese, 2007). Given the downturn in newspaper readership in the past decades, especially among the youngest generation, these findings raise concerns. If TV and internet news sources cannot replace the informational value of newspapers, how will future
generations acquire the confidence in their competence to participate in the political process?

The analysis presented in this chapter provides a partial answer to this question. According to the results digital natives are indeed best informed through the Internet. However, this is under the condition that they take an active role in the communication process. Similar to the findings of Chapter 3, I find again that mere exposure does not lead to political learning. Information needs to be processed in order to be effective. If adolescents are part of message construction, be it by engaging in an online discussion or merely by forwarding a political message to their peers, their level of internal political efficacy rises significantly. The effect is stronger than the effects of usage of any of the more passive form of news, including newspapers. These results fit well into the communication mediation model proposed by McLeod and his colleagues (McLeod, Shah, Hess, & Lee, 2010). By communicating about political messages interpersonally, online or offline, adolescents process information and become more engaged.

Yet, as promising as these findings are, the data also shows a key problem, which is that civic messaging is not widely spread. Less than 15% of the sample has ever engaged in civic messaging. Compared to the wide reach of TV news (over 80% report to watch TV news at least once a week), this is a rather small share. Given that watching TV news has no significant impact on an increase in internal efficacy, I can conclude that a large share of young adults today does not use news media in a way that fosters internal political efficacy. This might explain the declining levels of turnout among young voters in Netherlands and elsewhere in recent years (CBS). On the other hand, these results also indicate that European adolescents are not as “tuned out” as their American counterparts (Mindich, 2005). Even though it had no impact on change in internal efficacy, at least over 80% report to follow the news on TV on a regular basis.

Turning to the effect of internal efficacy on turnout my results echo recent findings from the United States (Glasford, 2008): Internal efficacy is a key driver of turnout in elections at a young age. As political involvement in the first elections has a strong socializing effect (Sears & Valentino, 1997) and predetermines
political engagement throughout the life course, it becomes apparent why understanding the pathway to political participation is so important. If young citizens are socialized in a way that leaves them feeling competent enough to take an electoral decision when it is their first time to vote, they are likely to become engaged citizens throughout their life.

This implies that measures aimed at increasing the low turnout rates among young voters, could be effective, if they are intended to foster young citizen’s confidence in their understanding of politics. This could be achieved through political education in schools, but also through media education. However, it would not be enough to simply prescribe the young to use the news. In this study it has become apparent that the degree to which the user is involved in the message is of crucial relevance. Furthermore, research has shown that the topic and other characteristics of the news also have an impact on potential effects. Strategically framed news, for example, is likely to raise political cynicism among the young and can ultimately lead to a refusal of major policy decisions taken by the government (Elenbaas, & de Vreese, 2008). News media content of high relevance to the young like coverage of developments in education policy, on the other hand, is likely to increase internal political efficacy because mediated information is processed more efficiently if it relates to the everyday life of an individual (Fisch, 2009; see also chapter 5).

The models presented in this chapter are based on panel data collected over the course of over two years. This has advantages as well as disadvantages. One of the main disadvantages of collecting panel data among such a young age group is that the panel attrition is relatively high. Over the course of two years we have lost more than half of the respondents. And even though that has not lead to a significantly different demographic composition of the panel, there is no certainty that there is no significant systematic attrition with regard to my dependent and independent variables. On the other hand, panel data provide the unique opportunity to study change in a dependent variable rather than a status at a specific point in time. Hence, if a relationship is found we can be confident that it is not a spurious correlation caused by a third unobserved variable. If I had
analyzed just a singular wave of my study, there would have been strong significant relationships of all of news use variables and internal political efficacy.

A two year time frame during late adolescents (age 16 to 18) provides an interesting insight into political socialization processes during formative years. However, we know that the process of political socialization starts at a much younger age and continues throughout the life course (Sears & Levy, 2003). In order to get a full picture of the processes and mechanisms future research should extend the longitudinal scope even more.
