** Department of Economics, Boston University

Part of this paper was written when Prof. Perotti visited the Research Department of the IMF. We thank Ingo Vogelsang and an anonymous referee for very useful comments.

Introduction

In recent years a vast transfer of state-owned assets to the private sector has taken place in many countries, irrespective of their level of development or the political affiliation of their government. Privatization is believed to improve economic incentives; attract managerial and technological resources from the private sector; broaden share ownership; and reduce public sector borrowing. In fact, privatization can be interpreted as an alternative form of public financing, a sort of "equity financing" to reduce the overhang of public debt, as the budget gains from the higher value of the firm under private ownership. In fact, the historical evidence indicates that state-owned enterprises have systematically drained public resources rather than contributed earnings, particularly in the Third World (World Development,[18]).

We document strong regularities in privatization programs across several countries. The data indicate a predominance of partial, staggered sales. Even though transfer of control typically takes place rapidly, governments tend to retain a significant stake for long intervals of time. The paper also examines the traditional argument for gradual sales, namely limited market capacity, with a confidence-building rationale.

Even after privatization restrains government interference, a firm is still exposed to the risk of adverse policy changes, particularly when it operates in a monopolistic market. A selling government will face investors' diffidence about its policy intentions after the sale; it may therefore structure the sale as to build policy credibility and maximize proceeds. To enhance investors' confidence, a selling government may signal commitment to current policy by retaining a stake in the firm for some time (while transferring managerial control), thus showing willingness to bear

some financial cost of policy changes; as time passes without a policy reversal, confidence and thus sale prices improve. In addition, early sales may be deliberately underpriced in order to convince the market to absorb larger sales, which reduce the risk born by the government and therefore enhance policy risk.

While the two explanations have similar empirical implications, our informal evaluation of the evidence appears more favorable to the reputation-building hypothesis than to the notion of temporary market capacity constraints. Presumably, the risk and the extent of policy change is largest for monopolistic industries or firms in protected markets, while firms operating in competitive markets are less subject to the threat of quasi rent appropriation. We find evidence that firms in such policy-sensitive sectors tend to be privatized with smaller initial sales and larger underpricing, and possibly requiring a longer time horizon before the share retained by the government can be sold. Complete sales are on average associated with manufacturing firms in competitive markets, while sales of utilities with potential monopolistic rents are more distributed over time.

We document that retained stakes are explicitly meant to be sold gradually over a few years. Often, stakes in several firms are sold simultaneously, creating considerable government risk sharing across industries. The profile of privatization proceeds increases over time, suggesting gradual selling calibrated to build investors confidence. As policy credibility increases, larger initial sales become more frequent.

We also document extensive underpricing, which is on average greater in privatization sales than in initial public offerings (IPO) of private firms. Underpricing appear to be largest for firms with large taxable rents, such as utilities. This is consistent with a signalling argument, since these firms are exposed to greater policy risk, and inconsistent with an asymmetric information

explanation over asset values, since these firms tend to be large and well known relative to private IPOs.

Section I interprets privatization as an enhanced commitment to reduced policy interference which reinforces incentives. Even after a sale, however, a sovereign government still retains considerable ability to affect the value of a firm sold. This has implications for the structure of privatization sales: specifically, policy risk can be resolved only through a maintained policy over time; and therefore, gradual sales may maximize sale proceeds. Section II presents data from several large privatization plans, and offers an informal evaluation of the empirical support for the reputation building hypothesis.

Section I A Rationale for Privatization

There is evidence that state-owned firms are less profitable than comparable private firms (e.g., Boardman and Vining,[3]; Megginson et al.[13]; Galal et al.[5]). Evidence of lower profitability does not prove by itself that public ownership is undesirable, since public firms may be pursuing worthy purposes other than profit maximization. For instance, higher profits in the private sector may derive from the exercise of market power.¹ However, it is not clear why public policy needs to be pursued through state ownership rather than by arm's length regulation, particularly if private ownership is desirable on the ground of efficiency. Even the argument that state ownership might overcome information asymmetries relevant for regulatory purposes can at most justify partial ownership or board membership, and certainly not state control.² In fact, the British experience indicates that the process of public regulation actually improved because of privatization, becoming more openly scrutinized.

Two related questions are just as important. Why should private ownership be necessary for

¹ It is in fact at best unclear whether state firms are more restrained in exploiting lack of competition, although monopoly power may manifest itself in lower quality and efficiency rather than high prices. Many state firms rely on exclusive licenses: public monopolies are common in telecommunications, oil, electricity, railways, utilities. Competition is often explicitly prohibited.

² An opposite view holds that public ownership actually aims at suppressing information about the extent of benefits to favored constituencies. The literature on rent-seeking behavior maintains that economic rents associated with control over public policy are easily captured by interest groups. Privatization can then ensure that regulation is more exposed to public scrutiny.

improved efficiency? Why could a government not minimize costs while pursuing its policy?

The property rights school (Alchian [1]), interprets public ownership as non transferrable common ownership, which reduces incentives by not allowing firm stakeholders to receive the capitalization of future earnings through the sale of property rights. This view ignores the possibility of privatization; it also does not explain why agents could not be given transferrable income rights distinct from property rights.

Stiglitz and Sappington [16] argue that public control reduces the cost of intervention to the policymaker; however, it also limits its ability to commit. Their analysis, however, leaves unclear the nature of costs of intervention and limited commitment. In Perotti [14], a rationale for privatization is presented, based on the residual nature of property rights. The idea is that under public ownership the government retains unconditional control over the use of firm assets; this discretionary power is very costly because it encourages rent seeking behavior by firm insiders, which represent a more coordinated interest group than dispersed taxpayers. Even if a government may in principle prefer to minimize costs, it is vulnerable to political pressure to maintain established rents (such as high wages/low effort, high and secure employment, favor to domestic suppliers etc); this leads to loss of incentives. In contrast, a private owner has both an incentive and the ability to commit contractually to reward efficient behavior.

In this view, privatization establishes a firmer commitment by the state because property rights are constitutionally protected against direct state interference. However, the transfer of property rights does not eliminate arm's length policy risk. Control over implementation of legislation still allows the government discretion to redistribute part of firm value, through new regulation, taxation, deregulation of entry, etc. A sovereign government cannot commit to maintain

its current policy in the future, even when it is in part enshrined in detailed legislation or semi-independent legislation; often only a policy maintained over time will gradually eliminates the perception of political risk.³

This raises the issue of which instruments the government has to signal commitment. In private initial public offerings (IPOs) there is also an adverse selection problem faced by investors, since the seller has presumably better information on the value of assets. The literature on IPOs has demonstrated that partial sales may be employed as signalling devices (Leland and Pyle,[10]). More recently, several authors (Allen and Faulhaber [2], Grinblatt and Hwang [6], Welch [18]) have shown that underpricing may be also interpreted as a signal of high value of assets.

One difficulty with a direct application of these models to a privatization sale is the assumption that a government knows more about asset values than the private sector, which seems implausible. Vickers and Yarrow [19] argue the opposite is likely to be true. Another hypothesis is that in the case of privatization sales the information asymmetry over firm value concerns the preferred choice of policy of the selling government. Perotti [14] extends the partial sale/underpricing model to the case of privatization, and shows that a committed government can improve its reputation with investors by transferring control immediately to the private sector, but initially selling only a fraction of the shares, retaining the remainder for a certain time period. As in the literature, the underpricing of the stock sale may also contribute to signal greater commitment.

The intuition gained by the model is that a government with no intention to interfere is

³ Confidence may take time to develop in part because a government may dissimulate their policy intent for some time, in order to obtain higher sale prices or more private investment in the firms sold. Thus there is a minimum holding period necessary to achieve higher confidence.

inherently more willing to retain a (noncontrolling) stake in the firm for some time period, since it knows that it will sell it at a high price in the future once its credibility has grown. Conversely, a government which expects to change its current policy prefers a rapid sale, since it expects reduced profits from the policy change and a lower market value for the firm. Similarly, underpricing may signal commitment because an uncommitted government cannot expect higher proceeds from a subsequent sale, and is therefore not willing to underprice the initial sale.

In conclusion, investors' valuation for the firm will be lower when the sale asks them to absorb a lot of policy risk in early stages. More generally, in a large privatization plan firms will be sold gradually, according to a timetable. Over time, in the absence of changes in policy the subsequent sales will fetch higher prices.

An alternative and popular rationale for gradual sales is that capital markets are capacity constrained in the short term. This view implies a temporarily highly inelastic demand for stocks. A very large stock sale in a small, segmented market may require investors to invest a large fraction of their wealth in the issue, and therefore demand a large risk premium. Then a rapid sale program would swamp the capital market, temporarily depressing share prices and reducing sale revenues. The speed of privatization is then constrained by the gradual increase in financial wealth available for equity investment.

The two views are difficult to distinguish empirically, because the reputation-building hypothesis also suggests that the sale price is lower for a larger sales, reflecting a rational inference by investors on policy intentions. We discuss the evidence in Section II.

The Separation of Income and Control Rights

Another rationale for underpricing arises once we realize that since stock provides voting rights, it is necessary to sell a minimum stake to offer to the private sector a reliable controlling majority. In fact, the initial sale may need to be larger than 50 % if there are coordination problems among private investors. But a larger sale has the effect of shifting more risk towards the private sector, which may not be interpreted favorably. In these circumstances, underpricing allows the state to sell more of the stock while still signalling commitment. This is also important when private incentives to invest in the firm depend, in addition to credibility, also on the fraction of residual profit they receive.

A reliable transfer of control may also be achieved simultaneously to signalling through an unbundling of the voting and residual income rights contained in corporate stock. In other words, the government could retain a significant amount of nonvoting stock while selling on the market all voting rights: this would signal willingness to bear risk while ruling out any intent to run the firm. There have been in fact a few examples of such arrangements, such as in the sale of Telmex (Telefonos de Mexico) and in bank privatization in Jamaica (Leeds, 1986). However, unbundling income and control rights may be impossible, perhaps because income rights alone may not be as unambiguously protected as property rights. Alternatively, the stock's voting rights may be suspended until the time of a final sale to the public.⁴

⁴ There are other contractual arrangements that allow such a separation. A prime example is the award to the private sector of a management contract, while the state retains ownership of the assets. However, this is at best a temporary solution, since it does not provide long term incentives.

The implications of the reputation-building conjecture for the time series of sales can be summarized in a few predictions. In general, the time profile of privatization proceeds should increase over time, since demand will tend to increase with the degree of confidence in public policy. Particularly at the beginning of the program, individual firms should be sold in stages; in a privatization plan involving the sale of several firms, the government should distribute their sales over time. Government statements on the retained stakes should indicate a complete sale within a certain time interval. As reputation for commitment increases, larger initial share offerings ought to become more frequent, while discounts decrease.⁵ In general, the probability of a policy change as well as its redistributive effect are greater for monopolistic industries operating in a rent-earning, protected market; in contrast, firms operating in a competitive market are subject to a lower threat of appropriation. The model predicts that firms in policy-sensitive sectors (monopolies, protected or subsidized manufacturers, etc.) will tend to be privatized with smaller initial sales and larger underpricing, and possibly a longer time horizon for the share retained by the government.

The next section presents transaction data from several privatization plans, and examines whether the evidence supports the reputation-building hypothesis.

Section II Empirical evidence and discussion

We present here suggestive evidence concerning several privatization programs in both developed and developing countries. Although the data comes from only a few countries, they

⁵In an econometric investigation of discounts, it is necessary to adjust for the risk profile of each firm (the sensitivity of its value to policy changes) as well as control for the amount of stock sold, since the formal analysis suggests that underpricing should increase with sale size.

represent some of the most extensive and successful programs.

The first four Exhibits refer to privatization programs from economically developed countries, namely France, the United Kingdom and Spain. A common character to all these cases is the presence of a well developed domestic capital market. We can therefore could evaluate the argument for gradual sales due to a limited capacity of the capital market to absorb the whole amount. The evidence suggests, however, that the structure of privatization sales does not differ across developed and underdeveloped markets. It seems also that many countries which initially had small equity markets (e.g. Mexico, Jamaica, Turkey) succeeded in promoting their growth through progressively large privatization sales and a stable policy.

Exhibits I and II document the history of public sales and proceeds in the UK program. There is a clear progression of sale volumes, which indicates an allocation of risk-bearing over time consistent with a model of reputation building. Exhibit II offers more detail on sales to the stock market. Note the tendency, particularly early in the program, to only partly privatize individual companies and retain large stakes in them for a few years. Some early partial sales are for the 51 % of stock, suggesting a symbolic transfer of a majority of voting rights. Complete sales seem to become common only at the end of the privatization program, presumably when the determination of the government to allow free rein to market forces had been established.

Data on French and Spanish transactions, portrayed in Exhibits III and IV, also suggest that partial sales are indeed common. Unfortunately, the French sample is quite short because the program was interrupted after a change in government.

Exhibits II, III and IV offer evidence on the remarkable extent of underpricing in these privatization programs. Although there are a few instances of undersubscribed issues in the UK, the

data suggests a remarkable and presumably deliberate choice of low offering prices. Note that in almost all cases where the price did not rise to a premium (excluding the sale of British Petroleum, whose price was set just prior to Black Monday for an offering on Oct. 30, 1987) the government sold the stock through an auction (tender sale) offer. This form of sale invites bids without a fixed price, so it ensures that the final price eliminates any excess demand. Thus the data offer evidence that when the UK Treasury chose to sell stock through a tender sale offer, it was able to capture the full market value of the company (Jenkinson and Mayer [8]). However, more often the government deliberately chose a form of sale (fixed price offerings) and a pricing which generated enormous excess demand, a phenomenon often anticipated in the press before the sale. The data on application multiples (the ratio of demand to supply at the offer price) gives an indication on the degree of excess demand at the fixed issue price. The resulting rationing was deliberately skewed in favor of smaller domestic investors, consistently with the government's policy to broaden share ownership. The goal of this policy was probably to create a class of investors which will resist policy changes adverse to the firm, thus binding future governments. This reinforces the view that the perception of policy commitment is crucial in privatization sales.

This evidence on underpricing should be compared with initial returns on private public offerings, a well-documented phenomenon for private IPOs. Interestingly, there is strong evidence (Jenkinson and Mayer [8]) that underpricing on privatization sales is even greater, both in the UK and France. This is very hard to reconcile with the prevailing explanation for discounting IPOs, which is based on the presence of better informed investors. While most private IPOs are relatively new and unknown companies, firms privatized in the UK and France were large and well-known companies with a long track record. Moreover, many of those showing the largest discounts were

utilities, which operate in less than competitive markets and whose revenues are fairly predictable.

A gradual sale may be interpreted as suggesting that the government had superior information over the value of the assets; if the private sector were better informed, as it seems natural, an auction sale would maximize proceeds. In contrast, the choice of a gradual sale and a high level of discounts suggests that the government needed to convey some strong signal. Underpricing may then be interpreted as an attempt by the government to signal political intent, and invest in credibility capital.

The signalling model suggests that as reputation for commitment increases, larger initial

share offerings may be preferred (in part to improve incentives), while discounts, controlling for sale size and specific firm risk, may decrease. In the case of the UK, the country with the longest data series, sales of larger stakes seem indeed to become more common over time. More recent privatization sales, such as the sale of Rolls Royce, British Airways or BAA, were in fact for the entire capital stock. This could be interpreted either as an improvement in the ability of the government to access equity markets because of improved confidence, or an exogenous increase in the share of financial wealth allocated to equity investment which relaxes the capacity constraints in the market.

The progressive decrease in discounts is quite clear in the French data, which is however a very short sample. There is less clear evidence in the UK case.⁷

The next Exhibit contains fairly detailed data on public sales in the Spanish privatization program. This sample is only a subset of all privatization sales. Once again, the evidence indicates a preference for partial initial sales, associated with a progressive dismissal of the remaining stake held by the government. These sales were fixed price offerings: the evidence on their pricing is consistent with deliberate underpricing, with discounts ranging as high as 100%. The data on application multiples also indicate enormous excess demand at the sale price. It is apparent that there were no binding market capacity constraints. Finally, we have no table on the time series of total privatization proceeds, since we do not have information on private sales, which were predominant in the Spanish program. However, one can infer from the column of proceeds from public sale the usual sharp progression in proceeds over time. Finally, the size of the stakes sold is much higher on average for the manufacturers such as AMPER, ACESA or ENCE than for the utilities such as GASMADRID or the oil company REPSOL, which is consistent with the reputation-building argument. Moreover, while the REPSOL was quite large, it seems hard to explain the limited size of the GASMADRID sale on the basis of its size.

⁷ However, the need for retaining a large stake will appear every time a firm for sale is in a sector which presents large quasi rents (as it is the case for firms in oligopolistic markets requiring large fixed investment, such as utilities). A track record of non-interference in the manufacturing industry (the object of many early sales) may not be sufficient evidence of a reluctance to tax away rents in firms such as British Telecom or the water utilities.

Exhibit V presents some aggregate data on the Chilean program. Two subperiods can be identified: a first massive transfer of assets to the private sector in 1974-1981, and a second wave of sales from 1986 onwards. Also in this case the progression of sales appears to increase over time in both subsamples.

The particular history of the Chilean experience deserves some attention. The first wave of sales was aimed at a very rapid transfer of majority stakes in a large number of firms to the private sector; as a result, it was biased towards sales to those private firms which could raise substantial amounts. Specifically, a small number of conglomerates had access to international capital markets,

and could finance large purchases through foreign borrowing. In addition, the government de facto financed a large amount of these sales by extending terms of payment over time. A traumatic recession with very high real interest rates in 1981-1982 caused the collapse of several of these overborrowed private groups. As a result, the state found itself forced to renationalize many of the firms sold. The second wave was financed more conservatively with a broader equity base and with a greater dispersion of buyers, which included many foreign firms.

The Chilean experience offers some important insights for privatization. We have so far focused on the effect of public policy commitment on incentives. However, private commitment may be just as important. For instance, the private buyer of state assets ought to be required to contribute an adequate amount of new capital to finance its purchase, in order to avoid creating perverse incentives for risk taking behavior which shifts the ultimate financial responsibility to the state in the form of contingent liabilities. Similarly, a commitment to new investment may be demanded from the private sector to rule out both high-risk strategies where the private owner gambles with the acquired assets with little new capital, or slows investment in capacity to maintain low output and oligopolistic profits.

Exhibit VI offers an interesting perspective on gradual sales. It describes in detail the plan for sequential sales of stakes in several firms to the private sector. It also contains information which allows to verify that the original plan was in fact executed rather precisely. Although there are some deviations from sale targets, perhaps reflecting some attention to market conditions, it is remarkable to see how the sale plan indicated in advance a gradual dismissal policy, to which it adhered quite closely.

Exhibits VII through XI present extensive data on the Nigerian, Turkish and Malaysian programs. Although our Nigerian data lack detailed information on the timing of sales, the extent of partial sales and their progression over time document a significant but temporary risk-bearing

role of the government. This is particularly evident in Exhibits VII and IX. However, this privatization program has certain specific features. In the first place, Exhibits VII and IX indicate that the government intends to sell its entire shareholdings in many firms (although we do not know whether this represents a final sale, implemented in stages). It can be argued that a sequence of complete sale of stock in individual firms, when distributed over time, is equivalent to a sequence of partial sales in a larger number of firms from the point of view of aggregate retained shareholdings. This may not establish policy credibility on a sector-by-sector basis; but a comparison of firms which are the object of complete and partial sales reveal that there is significant overlap of sectors. In addition, partial shareholding by the state appears to have been already important in the past; thus these complete divestitures may simply represent a final sale of firms in sectors over which the government has already established a certain policy credibility over time.

The information available on pricing of these sales is not very satisfactory for our purposes. The data presented on post-sale market prices comes from the same point in time for all firms; so we cannot measure underpricing, since post-sale changes in market valuation presumably have been different for different firms. It is significant, however, that all these later prices indicate a very strong value appreciation, which is suggestive of consistent and significant underpricing.

Exhibit X presents data from the Turkish privatization program. Here we are able to determine the timing of sales, which indicate the usual progression in amount sold.

Here, as before, partial sales appear to be the norm. Some earlier partial sales are of firms with considerable exposure to public policy changes, such as the telecommunications monopoly. Such a firm has very large capital investment and supplies the entire population; the political risk of redistribution of their quasi-rents is evident. Therefore, an early sale of such firms may establish credibility faster; as a populist government will be eager to intervene in these firms, the development over time of a reputation for commitment to current policy would be faster. The fact that no further sale of stock in these firms was made in the following two years seems consistent with a desire to establish a track record. Moreover, its initial sale exhibits the strongest underpricing. On the other hand, this is also a much larger sale than average, and it may be made gradually to avoid swamping the market. Moreover, it is not clear that the sale of monopolies should come earlier than the sale of enterprises in more competitive industries.

The data on pricing indicate that many sales traded at small or even negative premia, although the situation appears to have been reversed in more recent sales. Since we do not know whether these sales were tender offer rather than fixed price sales, it is impossible to tell whether the full pricing was deliberate.

Finally, Exhibit XI collects the information available on the Malaysian privatization program, one of the oldest in the developing world. The data is here quite complete, and therefore offers some scope in interpreting its evolution. The extent of underpricing is truly remarkable: the market price immediately after the sale jumps to an average premium of roughly 80 % from the offer price, while the application multiples suggests a demand on average ten times larger than supply. We find that the smaller stakes sold refer to sales of firms with a certain degree of domestic monopoly power, such as the national telecommunication company and the airline affiliate; presumably these companies are particularly vulnerable to the risk of changes in domestic regulatory policy, unlike the cement manufacturers or the hotel company. The case of the sale of the highly subsidized automobile manufacturer is probably similar, since the company relies heavily on a protective attitude by the government. Annual proceeds follow a rising progression, culminating in recent years in the sales of the Malaysian Telecom Syarikat. The timing of this delicate sale, six years after the onset of the program, is probably not accidental.

The early forms of privatization in Eastern Europe

A major test for the reputation-building approach presented here will be its ability to predict the form that the privatization plans in Eastern Europe will take in the next years.

However, privatization in Eastern Europe is certainly a more complex process for two reasons: the fact that most state owned firms are unprofitable, and the sheer enormity of the task. These elements suggest that a gradual approach may not be desirable. First, failure to attain rapidly a critical mass of privatized firms could lead to a much too slow improvement in productivity and to a collapse of the reform program (Roland and Verdier [15]). Second, for countries in difficult financial conditions, only a clear separation of firms' liabilities and the budget can avoid fiscal collapse. Finally, speed may be required to overcome the effect of a control vacuum over the corporate sector. As plan discipline has disappeared, labor and management are de facto in charge of most decisions; in the end-game period after privatization is announced but prior to firm private control, they are led to decapitalize the firms by appropriating or liquidating assets. A rapid transition to private owners and a clear separation from the government budget seems necessary to introduce some discipline and avoid further subsidization of inefficient production.

There is however a set of firms in these countries which are profitable, often because they command a strong market position, and have attracted foreign investors, for whom the risk of policy

changes is certainly a major consideration. The next exhibits describe the structure of sales to foreigners of these potentially profitable firms. Since these are private sales, data on pricing are unavailable. However, the evidence on the gradual transfer of shares and residual income rights is evident, even though it is well known that managerial control transfer is quite complete from the outset.

In addition, the mass privatization programs in these countries have elements consistent with

both capital scarcity (most certainly a major consideration) and confidence building. In Poland, for instance, the mass privatization scheme involves a combination of partial sales with underpricing. The plan calls for distributing 30 % of stock **free** to the general population through a voucher program; an additional deeply discounted sale of 20 % of the stock to the firms' employees, while the state sector would retain the remaining 50 % of stock for some time (Dhanij [4]). The structure of this privatization program is similar to programs announced later in other Eastern European countries, such as Romania and Bulgaria. It is noteworthy that while these governments are retaining significant stakes, they have already indicated their intention to sell them in just a few years' time.

Finally, the idea of free distribution of vouchers clearly represents an extreme form of underpricing. On the other hand, a voucher program is probably the only option available, given the extent of the transfer.

Future Research and Discussion

We have provided a set of data on privatization transactions which documents striking similarities across countries. Sales tend to be gradual; the government provides a temporary risk bearing role even well after it transfers control; and they are often underpriced.

One explanation is the existence of temporary market capacity constraints. Another is based on a confidence-building strategy by the selling government, in which willingness to retain a minority stake (as well as underpricing) signals a more reliable future policy and reassures investors, a crucial element for the success of a privatization program. However, the data available does not easily distinguish between the two hypotheses. In part is because they have similar empirical implications, that gradual sales are a mean of avoiding depressing prices by large sales, although for different reasons: in one case because of exogenous capacity constraints, in the other because investors make some inference over stock value from the amount sold.

A formal test would become possible only once more datapoints are collected. However, the limited evidence presented here seems more supportive of the reputation- building hypothesis. The predominance of partial sales is true across all countries, whatever the degree of development of the domestic capital market. Sale proceeds tend to increase sharply over time rather than match the

growth of private savings. Sales are deliberately underpriced, and to a greater degree than private IPOs. A casual evaluation of the evidence suggests that smaller initial sales, a long time interval between stock issues, and large underpricing of sales seem to be features more common for firms which are more policy-sensitive, such as natural or legal monopolies (utilities, concessions) or heavily subsidized/protected manufacturers.

Moreover, experience has shown that a stock market is able to absorb very large stock sales. The first British Telecom sale was three times larger than the previous largest share issue, but it was still oversubscribed several times. The Telmex sale was an even larger sale relative to the sale of the domestic market, but was a huge success.

It is puzzling that public sales are made through fixed-price offerings even though tender (auction) sales are in principle better at maximizing proceeds. These prices are set well below market values, as our data from application multiples and one-day return indicate. The recent literature on underpricing has suggested that it fulfills a signalling role; and while a government is not likely to have better information over asset values than the market, it certainly does over its policy intentions. To the extent that early credibility of policy also has an important effect on private investment, underpricing may be justified. Thus the pricing and sequencing of sales are substitutes: slower sales at full price would achieve the same result over a longer period than discounted sales. In general, when policy credibility has an important effect on investment, a more rapid privatization may be justified even if associated with greater discounts.

Although the confidence building view may explain the extent of underpricing, the issue is probably complex. The choice of underpricing offers the government the opportunity to determine the allocation of shares, which may be employed to induce wider share ownership. This policy goal is also consistent with a commitment motivation. A committed government may ration the allocation of shares with a bias towards the smaller investors, with the intention to create a large constituency vested in the success of privatization in order to reduce future political risk (and even bind a future government's action). However, this requires also the introduction of incentives to maintain these shareholdings for the long term in order to avoid immediate resale. Consistent with this point, the 1984 offering of British Telecom included a bonus to be paid in 1987 to buyers who still held the shares; similar vouchers were distributed at other UK sales.
