Evidence for Electroweak Production of $W^\pm W^\pm jj$ in $pp$ Collisions at $\sqrt{s} = 8$ TeV with the ATLAS Detector

G. Aad et al.*
(ATLAS Collaboration)
(Received 23 May 2014; published 3 October 2014)

This Letter presents the first evidence for electroweak production of $W^\pm W^\pm jj$, same-electric-charge diboson production in association with two jets, using 20.3 fb$^{-1}$ of proton-proton collision data at $\sqrt{s} = 8$ TeV recorded by the ATLAS detector at the Large Hadron Collider. Events with two reconstructed same-charge leptons ($e^\pm e^\pm$, $e^\pm \mu^\pm$, and $\mu^\pm \mu^\pm$) and two or more jets are analyzed. Production cross sections are measured in two fiducial regions, with different sensitivities to the electroweak and strong production mechanisms. First evidence for $W^\pm W^\pm jj$ production and electroweak-only $W^\pm W^\pm jj$ production is observed with a significance of 4.5 and 3.6 standard deviations, respectively. The measured production cross sections are in agreement with standard model predictions. Limits at 95% confidence level are set on anomalous quartic gauge couplings.

The scattering of two massive vector bosons (VBS), $VV \rightarrow VV$ with $V = W$ or $Z$, is a key process to probe the nature of electroweak symmetry breaking [1,2]. In the absence of a standard model (SM) Higgs boson, the longitudinally polarized VBS amplitude increases as a function of the center-of-mass energy $\sqrt{s}$ and violates unitarity at energies around 1 TeV [3-5]. The recent discovery of a 125 GeV SM-like Higgs boson at the Large Hadron Collider (LHC) [6,7] provides a plausible explanation for the mechanism that unitarizes this process. However, many physics scenarios predict enhancements in EW without considering the boson or two jets with $p_T > 25$ GeV, $|\eta| < 2.5$ [12], invariant mass $m_{\ell\ell} > 20$ GeV, and angular separation $\Delta R_{\ell\ell} \equiv \sqrt{(\Delta \phi)^2 + (\Delta \eta)^2} > 0.3$. At least two jets reconstructed with the anti-$k_T$ algorithm [13] with jet size $R = 0.4$ and with $p_T > 30$ GeV, $|\eta| < 4.5$, and separated from the leptons by $\Delta R_{\ell j} > 0.3$ are also required. The invariant mass of the two jets with the largest $p_T$ (m$_{jj}$) must be larger than 500 GeV, and the magnitude of the missing transverse momentum ($E_T^{miss}$) calculated using all neutrinos in the final state must be greater than 40 GeV. To reduce the dependence on QED radiation, lepton momenta include contributions from photons within $\Delta R = 0.1$ of the lepton direction. The second region or “VBS region” is a subset of the inclusive region that also requires the two jets with largest $p_T$ to be separated in rapidity [14] by $|\Delta y_{jj}| > 2.4$. This enhances the purity of electroweak $W^\pm W^\pm jj$ by removing most of the strong $W^\pm W^\pm jj$ events, which are considered as a background in this region.

The expected production cross sections for the $pp \to W^{\pm}W^{\pm}jj$ process in the two fiducial regions (“fiducial cross sections”) are calculated using POWHEGBOX [15,16], with CT10 parton distribution functions (PDFs) [17], interfaced with PYTHIA8 [18,19] for parton showering, hadronization, and underlying event modeling. The contribution from nonresonant production of the same leptonic final state is also considered, but is strongly suppressed [16]. The cross section for the electroweak $W^{\pm}W^{\pm}jj$ process is predicted to be $1.00 \pm 0.06 \text{ fb}$ in the inclusive region and $0.88 \pm 0.05 \text{ fb}$ in the VBS region. The cross section for the strong $W^{\pm}W^{\pm}jj$ process is $0.35 \pm 0.05 \text{ fb}$ in the inclusive region and $0.098 \pm 0.018 \text{ fb}$ for the VBS region. The uncertainty on these predictions include 68% confidence level PDF uncertainties [20], parton shower, and hadronization modeling uncertainties estimated by comparing PYTHIA8 and HERWIG++ plus JIMMY [21,22], the independent variation of renormalization and factorization scales by a factor of 2, the difference between the predictions from POWHEGBOX and VBFNLO [23], and the integration error. The parton shower and generator uncertainties are dominant for electroweak production, while scale variations are dominant for strong production. Interference between electroweak and strong production is studied at leading-order accuracy using SHERPA [24] and is found to increase the combined strong and electroweak $W^{\pm}W^{\pm}jj$ cross section by $(12 \pm 6)%$ in the inclusive region and $(7 \pm 4)%$ in the VBS region. The total SM signal cross-section prediction in the inclusive region is $1.52 \pm 0.11 \text{ fb}$, while the sum of electroweak and interference contributions in the VBS region is $0.95 \pm 0.06 \text{ fb}$.

The ATLAS detector described in Ref. [25] is a multipurpose particle physics detector. It consists of an inner tracking detector (ID) surrounded by a calorimeter and a muon spectrometer (MS). Events for this analysis are selected with single-lepton ($e$ or $\mu$) triggers. After applying data quality requirements, the remaining data set has a total integrated luminosity of $20.3 \pm 0.6 \text{ fb}^{-1}$ [26].

Electron candidates are reconstructed from a combination of a cluster of energy deposits in the electromagnetic calorimeter and a track in the ID. They are required to have $p_T > 25 \text{ GeV}$ and $|\eta| < 2.47$, excluding the transition region between the barrel and endcap calorimeters ($1.37 < |\eta| < 1.52$). Candidate electrons must satisfy the tight quality definition described in Ref. [27] and reoptimized for 2012 data taking. Muon candidates are reconstructed by combining tracks in the ID and MS [28]. The combined track is required to have $p_T > 25 \text{ GeV}$ and $|\eta| < 2.4$. Leptons are required to originate from the same interaction vertex and, to reduce nonprompt production, calorimeter and tracker isolation requirements are applied within a cone of size $\Delta R = 0.3$.

Jets are reconstructed from clusters of energy in the calorimeter, using the anti-$k_T$ algorithm with jet-size parameter $R = 0.4$ and calibrated using techniques from Ref. [29]. Only jets with $p_T > 30 \text{ GeV}$ and $|\eta| < 4.5$ are considered. Jets containing $b$ hadrons (“$b$ jet”) with $|\eta| < 2.5$ are identified by combining information on the impact parameter significances of their tracks and explicit secondary vertex reconstruction [30]. The measurement of $E_T^{\text{miss}}$ [31] is based on the energy collected by the electromagnetic and hadronic calorimeters, and muon tracks reconstructed by the ID and MS.

Candidate $W^{\pm}W^{\pm}jj$ events are required to have exactly two leptons (electrons or muons) with the same electric charge and at least two jets satisfying the above selection criteria. Three different final states (“channels”) are considered based on the lepton flavor, namely, $e^+e^-, e^\pm\mu^\pm$, and $\mu^\pm\mu^\mp$. To reduce the contributions from $WZ/\gamma^* + \text{jets}$ and $ZZ + \text{jets}$ production, events are removed if they contain additional leptons reconstructed with looser isolation requirements, $p_T > 7 \text{ GeV}$ (6 GeV) for electrons (muons) and loose quality definition for electrons [27]. The two leptons must have $m_{\ell\ell} > 20 \text{ GeV}$. The dielectron invariant mass must not be within 10 GeV of the $Z$ boson mass to reduce $Z + \text{jets}$ background from electron charge misidentification. Events are also required to have $E_T^{\text{miss}} > 40 \text{ GeV}$, and in order to reject backgrounds from nonprompt leptons, mainly $t\bar{t} \to \ell\nu jj b\bar{b}$, events must not contain a $b$ jet. To further reduce $t\bar{t}$ and $WZ/\gamma^* + \text{jets}$ backgrounds, events in the inclusive region are required to have $m_{jj} > 500 \text{ GeV}$. In addition, in the VBS region $|\Delta y_{jj}| > 2.4$ is required.

Monte Carlo (MC) simulation is used to estimate the expected signal events. The $W^{\pm}W^{\pm}jj$ processes are generated with SHERPA, using up to three jets in the matrix-element and parton shower model [24], and normalized using the expected cross section in each fiducial region (see above). Generated events are processed with the full detector simulation [32] based on GEANT4 [33], and the standard ATLAS reconstruction software.

Several SM processes enter the $W^{\pm}W^{\pm}jj$ signal regions as irreducible physics processes or through instrumental effects. About 90% of the expected prompt lepton background originates from $WZ/\gamma^* \to \ell^\pm\ell^\pm\nu\nu$ production that passes signal region selections when one lepton is outside of the experimental acceptance or does not satisfy the lepton identification criteria. Up to 20% of the expected $WZ/\gamma^*$ contribution comes from electroweak production. Smaller contributions from $ZZ + \text{jets}$ and $t\bar{t} + W/Z$ are also considered. These “prompt lepton backgrounds” are estimated using MC simulation. In the VBS region strong $W^{\pm}W^{\pm}jj$ is estimated using simulation and normalized to the SM prediction for the fiducial cross section described above. Correction factors for lepton and jet efficiencies, additional $pp$ interactions (pile-up), and beam-spot location are applied to the simulation to account for differences with data. Furthermore, the simulation is tuned to reproduce the calorimeter response and the muon momentum scale and resolution observed in data. Systematic uncertainties on the
signal yield and backgrounds estimated from MC simulation are derived from uncertainties on the correction factors, energy smearing parameters, the $E_t^\mathrm{miss}$ modeling, and the $b$-tagging efficiency and mistag rate [30].

SHERPA is used to produce $W^+/\gamma^* + jets$ events, taking into account both the strong and electroweak production mechanisms. This sample is normalized to the next-to-leading-order calculation in QCD from VBFNLO in each fiducial region [34,35], with an accuracy of 14% in the inclusive region and 11% in the VBS region. The SHERPA extrapolation from the inclusive region to the VBS region differs from the VBFNLO calculation by 3%. The main sources of uncertainties on the VBFNLO normalization are from the PDF, from factorization and renormalization scale dependence, and from the parton shower model. The small $t\bar{t}Zj$ component in this sample is estimated using the SHERPA prediction.

The production of $ZZ + jets$ is modeled with SHERPA, while for $t\bar{t} + W/Z$ processes MADGRAPH [36] with PYTHIA8 is used. The theoretical uncertainties on the production cross sections of these processes are ±19% and ±30%, respectively, dominated by the jet multiplicity modeling and the scale uncertainties.

Contributions from $W\gamma$ production, including electroweak production of $W\gamma jj$, where the photon converts to an electron-positron pair inside the detector is included in the “conversion background.” It is estimated using ALPGEN [37] with HERWIG plus JIMMY and SHERPA (for electroweak $W\gamma jj$) MC samples with a total theory uncertainty of ±17%.

The remaining conversion background originates from processes that produce oppositely charged prompt leptons where one lepton’s charge is misidentified, primarily because one electron has undergone hard bremsstrahlung and subsequent photon conversion. This background is estimated from data. The dominant origins of this background are $t\bar{t} \rightarrow \ell\ell\nu\nu b\bar{b}$ and Drell-Yan lepton pair production. The electron charge misidentification rate is measured using $Z/\gamma^* \rightarrow e\mu$ events. The muon charge misidentification rate is found to be negligible. The background is estimated by applying the electron charge misidentification rate to data selected using all signal selection criteria except for the electric charges of the leptons, which are instead required to be opposite sign. The dominant systematic uncertainties arise from possible method bias (studied in simulation) and the statistical uncertainty in the charge misidentification rate. The total uncertainty is between 15% and 32% depending on signal region and channel.

Contributions from SM processes that produce at least one nonprompt lepton from hadron decays in jets ($W + jets, t\bar{t}$, single top or multijet production, denoted by “other nonprompt background”) are estimated from data events that contain one lepton passing all selections and one nonisolated or loose-quality lepton. These events, which are dominated by the nonprompt background, are scaled by a “fake rate” to predict the nonprompt background. The fake rate is the efficiency for nonprompt leptons to pass the nominal lepton selections with respect to the looser isolation and quality requirements. The fake rate for nonprompt leptons is measured in a dijet sample. The uncertainty on the nonprompt background estimate is between 39% and 52% depending on region and channel, dominated by prompt-lepton contamination in the dijet sample and the uncertainty on the extrapolation of fake rates into the signal region.

Contributions from double parton scattering [38] arise mainly in $W^+/\gamma^*$ and dijet production. However, simulation shows they are negligible after the requirement of $m_{jj} > 500$ GeV.

Background predictions are tested in several same-electric-charge dilepton control regions summarized in Table I. The MC modeling of prompt backgrounds is tested in a trilepton control region defined by inverting the third-lepton veto and removing the $|\Delta y_{jj}|$ and $m_{jj}$ selections. Conversion and prompt backgrounds are tested in a region with at most one jet ($\leq 1$ jet, in Table I). In this sample the $e^+e^-$ channel is dominated by $Z \rightarrow ee$ events, the $\mu^+\mu^-$ channel is dominated by prompt processes, and the $e^+\mu^-$ channel has a mixture of prompt, nonprompt, and conversion backgrounds. Backgrounds from nonprompt leptons originating from $t\bar{t} \rightarrow \ell\nu jj b\bar{b}$ are tested in a control region that requires at least one of the jets to be identified as a $b$ jet. Finally, the combined background model is tested by inverting the $m_{jj}$ selection.

The observed number of events is compared in Table II to the expected yield from Table I. The combined significance over the background-only region is observed in both signal regions and in all three channels; the combined significance over the background-only region is observed in both signal regions and in all three channels; hypothesis is 4.5 standard deviations in the inclusive region and 3.6 standard deviations in the VBS region. The expected significance for a SM $W^\pm W^\pm jj$ signal is 3.4 standard deviations in the inclusive region and 2.8 in the VBS region.

Figure 1 shows the expected and observed $m_{jj}$ distribution after all inclusive region selection criteria are applied, except $m_{jj} > 500$ GeV. Figure 2 shows the $|\Delta y_{jj}|$ distribution after the inclusive region selections. All three dilepton channels are summed in both figures. The observed excess is consistent with the expected event topology for $W^\pm W^\pm jj$ production.

We interpret the excess over background as $W^\pm W^\pm jj$ production, and the fiducial cross sections in the two regions ($\sigma_{\text{fid}}$) are measured by combining the three decay channels in a likelihood function. Systematic uncertainties are taken into account with nuisance parameters.

The signal efficiency in each fiducial region is defined as the number of observed signal events after selections divided by the number of expected signal events after selections divided by the number of expected signal events after selections divided by the number of events passing the respective fiducial region selections at the particle level. The efficiency accounts for the detector reconstruction, migration into and out of the fiducial volume, identification, and trigger efficiency; it is 56%, 72%, 77% for the inclusive region and 57%, 73%, 83% for the VBS region in the $e^+e^-$, $e^+\mu^-$, and $\mu^+\mu^-$ channels, respectively. The efficiency also accounts for the contribution of leptonic $\tau$ decays, which are not included in the fiducial cross-section definition: 10% of signal candidates are expected to originate from leptonic $\tau$ decays. The uncertainty on the signal efficiency is dominated by the jet reconstruction uncertainty of 6%.

The measured fiducial cross section for strong and electroweak $W^\pm W^\pm jj$ production in the inclusive region...
is $\sigma_{\text{fid}} = 2.1 \pm 0.5\,(\text{stat}) \pm 0.3\,(\text{syst})$ fb. The measured fiducial cross section for electroweak $W^\pm W^\pm jj$ production, including interference with strong production in the VBS region, is $\sigma_{\text{fid}} = 1.3 \pm 0.4\,(\text{stat}) \pm 0.2\,(\text{syst})$ fb. The measured cross sections are in agreement with the respective SM expectations of 1.52 $\pm$ 0.11 fb and 0.95 $\pm$ 0.06 fb.

Additional contributions to $W^\pm W^\pm jj$ production can be expressed in a model-independent way using higher-dimensional operators leading to anomalous quartic gauge boson couplings (AQGCs). The measured cross section in the VBS fiducial region is used to set limits on AQGCs affecting vertices with four interacting $W$ bosons. The WHIZARD event generator [39] is used to generate $W^\pm W^\pm jj$ events with AQGCs using a $K$-matrix unitarization method [40]. Following existing notations [40,41], deviations from the SM (which includes a SM Higgs with $m_H = 126$ GeV) are parametrized in terms of two parameters ($\alpha_4$, $\alpha_5$). The reconstruction efficiency is derived using simulated WHIZARD samples combined with PYTHIA8. The difference with respect to SHERPA for the SM case is taken as additional systematic uncertainty. The reconstruction efficiency increases with increasing $\alpha_{4,5}$ values, but the effect is small compared to the increase in the fiducial cross sections in the same parameter space. The expected and observed 95% confidence intervals derived from the profile likelihood function are shown in Fig. 3. The one-dimensional projection at $\alpha_{4,5} = 0$ is, respectively, $-0.14 < \alpha_4 < 0.16$ and $-0.23 < \alpha_5 < 0.24$, compared to an expected $-0.10 < \alpha_4 < 0.12$ and $-0.18 < \alpha_5 < 0.20$.

In conclusion, a significant excess of events over background predictions is found using 20.3 fb$^{-1}$ of $pp$ collision data at $\sqrt{s} = 8$ TeV recorded by the ATLAS detector at the LHC. This excess is consistent with SM $W^\pm W^\pm jj$ production. Two fiducial cross sections are measured in regions with different sensitivities to the electroweak and strong $W^\pm W^\pm jj$ processes. The measured cross sections are in good agreement with SM predictions. In addition, the first limits on the $\alpha_{4,5}$ AQGC parameters are set.

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently. We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWF and FWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST, and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR, and VSC CR, Czech Republic; DNRF, DNSRC, and Lundbeck Foundation, Denmark; EPLANET and ERC, European Union; IN2P3-CNRS, CEA-DSM/IRFU, France; GNSF, Georgia; BMBF, DFG, HGF, MPG, and AvH Foundation, Germany; GSRT, Greece; ISF, MINERVA, GIF, DIP, and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRS, Morocco; FOM and NWO, Netherlands; BRF and RCN, Norway; MNiSW, Poland; GRICES and FCT, Portugal; MERYS (MECTS), Romania; MES of Russia and ROSATOM, Russian Federation; JINR; MSTD, Serbia; MSSR, Slovakia; ARRS and MVZT, Slovenia; DST/NRF, South Africa; MICINN, Spain; SRC and Wallenberg Foundation, Sweden; SER, SNSF, and Cantons of Bern and Geneva, Switzerland; NSc, Taiwan; TAEK, Turkey; STFC, the Royal Society, and Leverhulme Trust, United Kingdom; DOE and NSF, United States of America. The crucial computing support from all WLCG partners is acknowledged gratefully, in particular from CERN and the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INFN-CNAF (Italy), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (UK) and BNL (USA) and in the Tier-2 facilities worldwide.
ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the center of the detector and the $z$ axis along the beam pipe. The $x$ axis points from the IP to the center of the LHC ring, and the $y$ axis points upward. Cylindrical coordinates $(r, \phi)$ are used in the transverse plane, $\phi$ being the azimuthal angle around the beam pipe. The pseudorapidity is defined in terms of the polar angle $\theta$ as $\eta = -\ln(\tan(\theta/2))$. Transverse projections are defined relative to the beam axis.

Rapidity is defined as $y = (1/2) \ln[(E + p_z)/(E - p_z)]$.
