Abstract. We investigate the structure of the Medvedev lattice as a partial order. We prove that every interval in the lattice is either finite, in which case it is isomorphic to a finite Boolean algebra, or contains an antichain of size $2^{\aleph_0}$, the size of the lattice itself. We also prove that it is consistent with ZFC that the lattice has chains of size $2^{\aleph_0}$, and in fact that these big chains occur in every infinite interval. We also study embeddings of lattices and algebras. We show that large Boolean algebras can be embedded into the Medvedev lattice as upper semilattices, but that a Boolean algebra can be embedded as a lattice only if it is countable. Finally we discuss which of these results hold for the closely related Muchnik lattice.

§1. Introduction. Medvedev [4] originally introduced the lattice that now bears his name in order to establish a connection with intuitionistic logic, following up on a rather informal idea of Kolmogorov. Later the lattice, which we will denote by $\mathfrak{M}$, was studied also as a structure of independent interest, being a generalization of structures such as the Turing degrees and the enumeration degrees that are contained in $\mathfrak{M}$ as substructures. For example, Muchnik phrased his original solution to Post’s problem [5] as a result in the context of the Medvedev lattice.

Let us briefly recall the definition of $\mathfrak{M}$. Let $\omega$ denote the natural numbers and let $\omega^\omega$ be the set of all functions from $\omega$ to $\omega$ (Baire space). A mass problem is a subset of $\omega^\omega$. Every mass problem is associated with the “problem” of producing an element of it. A mass problem $\mathcal{A}$ Medvedev reduces to mass problem $\mathcal{B}$, denoted $\mathcal{A} \leq_M \mathcal{B}$, if there is a partial computable functional $\Psi: \omega^\omega \to \omega^\omega$ defined on all of $\mathcal{B}$ such that $\Psi(\mathcal{B}) \subseteq \mathcal{A}$. That is, $\Psi$ is a uniformly effective method for transforming solutions to $\mathcal{B}$ into solutions to $\mathcal{A}$. The relation $\leq_M$ induces an equivalence relation on mass problems: $\mathcal{A}$ and $\mathcal{B}$ are $M$-equivalent, denoted $\mathcal{A} \equiv_M \mathcal{B}$, if $\mathcal{A} \leq_M \mathcal{B}$ and $\mathcal{B} \leq_M \mathcal{A}$. The equivalence class of $\mathcal{A}$ is denoted by $\deg_M(\mathcal{A})$ and is called the Medvedev degree, or simply $M$-degree, of $\mathcal{A}$. We denote Medvedev degrees by boldface symbols. There is a smallest Medvedev degree, denoted by $\mathbf{0}$, namely the degree of any mass problem containing a computable function, and there is a largest degree $\mathbf{1}$, the degree of the empty mass problem, of which it is absolutely impossible to produce an element. Finally, it is possible to
define a meet operator $\times$ and a join operator $+$ as follows: For functions $f$ and $g$, as usual define the function $f \oplus g$ by $f \oplus g(2x) = f(x)$ and $f \oplus g(2x + 1) = g(x)$. Let $n^\prec \mathcal{A} = \{ n^\prec f : f \in \mathcal{A} \}$, where $\prec$ denotes concatenation. Define
$$
\mathcal{A} + \mathcal{B} = \{ f \oplus g : f \in \mathcal{A} \land g \in \mathcal{B} \}
$$
and
$$
\mathcal{A} \times \mathcal{B} = 0^\prec \mathcal{A} \cup 1^\prec \mathcal{B}.
$$
The structure $\mathfrak{M}$ of all Medvedev degrees, ordered by $\leq_M$ and together with $+$ and $\times$, forms a distributive lattice. Medvedev [4] also showed that it is possible to define an implication operator $\rightarrow$ on $\mathfrak{M}$, that is, $\mathfrak{M}$ is a Brouwer algebra. But this will not concern us in the present paper since we will mainly be studying $\mathfrak{M}$ as a partial order, although the lattice operators on $\mathfrak{M}$ will play an important role throughout. For more information and discussion we refer to the following literature. An early reference is Rogers’ textbook [10], which contains a discussion of the elementary properties of $\mathfrak{M}$. Sorbi [14] is a general survey paper about $\mathfrak{M}$. Sorbi and Terwijn [15] is a recent paper discussing the connections with constructive logic. Simpson [12] surveys Medvedev reducibility on $\Pi^0_1$ classes, especially with an eye to the connection with algorithmic randomness. Binns and Simpson [1] are concerned with lattice embeddings into the Medvedev and Muchnik lattices of $\Pi^0_1$ classes.

Our notation is mostly standard and follows Odifreddi [7] and Kunen [3]. $\Phi_e$ is the $e$-th partial computable functional. For $f \in \omega^\omega$ we let $f^-$ be the function with $f^-(x) = f(x + 1)$ (i.e., $f$ with its first element chopped off) and for a set $\mathcal{X} \subseteq \omega^\omega$ we let $\mathcal{X}^- = \{ f^- : f \in \mathcal{X} \}$. We use $2^\omega$ to denote the Boolean algebra of all subsets of $\{ 0, \ldots, n - 1 \}$ under inclusion. For countable sets $I \subseteq \omega$ and mass problems $\mathcal{A}_i$, $i \in I$, we have the generalized meet operator
$$
\prod_{i \in I} \mathcal{A}_i = \{ i^- f : i \in I \land f \in \mathcal{A}_i \}.
$$
One easily checks that for finite $I$ this is $M$-equivalent to an iteration of the meet operator $\times$. If $a \leq b$ in some partial order, we use the interval notation $[a, b] = \{ x : a \leq x \leq b \}$. Similarly $(a, b)$ denotes an interval without endpoints.

§2. Intervals in the Medvedev lattice. In this section we prove that every interval in the Medvedev lattice is either finite of exponential size or contains an antichain of the cardinality of the full lattice, namely $2^{2^{\aleph_0}}$. We first repeat from Sorbi and Terwijn [15] the basic strategy for obtaining incomparable elements that avoid upper cones. We subsequently generalize this construction to obtain larger and larger antichains.

**Lemma 2.1** (Sorbi and Terwijn [15]). Let $\mathcal{A}$ and $\mathcal{B}$ be mass problems such that
$$
\forall \mathcal{C} \subseteq \mathcal{A} \text{ finite } (\mathcal{B} \times \mathcal{C} \not\leq_M \mathcal{A}).
$$
Then there exists a pair $\mathcal{C}_0, \mathcal{C}_1$ of $M$-incomparable mass problems $\mathcal{C}_0, \mathcal{C}_1 \not\leq_M \mathcal{A}$ such that $\mathcal{B} \times \mathcal{C}_0$ and $\mathcal{B} \times \mathcal{C}_1$ are $M$-incomparable. (In particular, neither of $\mathcal{C}_0$ and $\mathcal{C}_1$ is above $\mathcal{B}$.)

**Proof.** We want to build $\mathcal{C}_0$ and $\mathcal{C}_1$ above $\mathcal{A}$ in a construction that meets the following requirements for all $e \in \omega$:
\(R_0^*: \Phi_e(\mathbb{C}_0) \subseteq B \times C_1.\)
\(R_1^*: \Phi_e(\mathbb{C}_1) \subseteq B \times C_0.\)

The \(\mathbb{C}_i \subseteq A \times A \equiv_M A\) will be built as unions of finite sets \(\bigcup_i \mathbb{C}_{i,s}\), such that \(\mathbb{C}_{i,s} \subseteq A \times A\) for each pair \(i,s\). We start the construction with \(\mathbb{C}_{i,0} = \emptyset\). The idea to meet \(R_0^*\) is simple: By condition (1) we have at stage \(s\) of the construction that \(B \times C_{1,s} \not\subseteq_M A\), so there is a witness \(f \in A\) such that \(\Phi_e(f) \notin B \times C_{1,s}\).

(Either by being undefined or by not being an element of \(B \times C_{1,s}\)) We put such a witness into \(\mathbb{C}_0\). Now this \(f\) will be a witness to \(\Phi_e(\mathbb{C}_0) \not\subseteq B \times C_1\) provided that we can keep future elements of \(\mathbb{C}_1\) distinct from \(\Phi_e(f)\). The problem is that some requirement \(R_1^*\) may want to put \(\Phi_e(f)\) into \(\mathbb{C}_1\) because \(\Phi_e(f)(0) = 1\) and the function \(\Phi_e(f)\) is the only witness to \(\Phi_e(A) \not\subseteq B \times C_0\). To resolve this conflict it suffices to complicate the construction somewhat by prefixing all elements of \(A\) by an extra bit \(x \in \{0,1\}\), that is, to work with \(A \times A\) rather than \(A\). This basically gives us two versions of every potential witness, and we can argue that either choice of them will be sufficient to meet our needs, so that we can always keep them apart.

We now give the construction in technical detail. We build \(\mathbb{C}_0, \mathbb{C}_1 \subseteq A \times A\).

**Stage \(s = 0\):** Let \(\mathbb{C}_{0,0} = \mathbb{C}_{1,0} = \emptyset\).

**Stage \(s + 1 = 2s + 1\):** We take care of \(R_0^*\). We claim that there is an \(f \in A - \mathbb{C}_{0,s}\)
and an \(x \in \{0,1\}\) such that

\[\exists h \in \mathbb{C}_{0,s} \cup \{x^cf\} (\Phi_e(h) \notin B \times (C_{1,s} \times C_{1,s})).\]

Namely, otherwise we would have that for all \(f \in A - \mathbb{C}_{0,s}\) and \(x \in \{0,1\}\)

\[\forall h \in \mathbb{C}_{0,s} \cup \{x^cf\} (\Phi_e(h) \in B \times (C_{1,s} \times C_{1,s})).\]

But then it follows that \(A \not\geq_M A \times (C_{1,s} \times C_{1,s})\), contradicting the assumption (1).

To see this, assume (3) and let

\[D = \mathbb{C}_{0,s} \cup \{x^cf: x \in \{0,1\} \land f \in A - \mathbb{C}_{0,s}\}.\]

Then \(B \times (C_{1,s} \times C_{1,s}) \not\subseteq_M D\) via \(\Phi_e\). But we also have \(D \subseteq_M A\), so we have \(B \times C_{1,s} \not\subseteq_M A\), contradicting (1). To show that \(D \subseteq_M A\), let \(D_{0,s} = \{f_1, \ldots, f_s\}\) and let \(\tilde{f}_i, 1 \leq i \leq s\), be finite initial segments such that the only element of \(\mathbb{C}_{0,s}\) extending \(\tilde{f}_i\) is \(f_i\). (Note that such finite initial segments exist since \(\mathbb{C}_{0,s}\) is finite.) Let \(x_i\) be such that \(x_i \tilde{f}_i \in \mathbb{C}_{0,s}\). Then \(D \subseteq_M A\) via

\[\Phi(f) = \begin{cases} x_i f & \text{if } \exists x_i \tilde{f}_i \subseteq f, \\ 0^cf & \text{otherwise} \end{cases}\]

So we can choose \(h\) as in (2). Put \(h\) into \(\mathbb{C}_{0,s+1}\). If \(\Phi_e(h) = \Gamma y^g\) for some \(g \in A - C_{1,s}\) and \(y \in \{0,1\}\) we also put \((1 - y)^g\) into \(\mathbb{C}_{s+1}\).

**Stage \(s + 1 = 2s + 2\):** The construction to satisfy \(R_1^*\) is completely symmetric to the one for \(R_0^*\), now using \(\mathbb{C}_{1,s}\) instead of \(\mathbb{C}_{0,s}\). This ends the construction.

We verify that the construction succeeds in meeting all requirements. At stage \(s + 1 = 2s + 1\), the element \(h\) put into \(\mathbb{C}_0\) is a witness for \(\Phi_e(\mathbb{C}_0) \not\subseteq B \times C_{1,s+1}\). In order for \(h\) to be a witness for \(\Phi_e(\mathbb{C}_0) \not\subseteq B \times C_1\) it suffices to prove that all elements \(x^cf\) entering \(C_1\) at a later stage \(t > 2s + 1\) are different from \(\Phi_e(h)^{-\gamma}\).

If \(\Phi_e(h)\) is not of the form \(\Gamma y^g\) for \(g \in A - C_{1,s}\) and \(y \in \{0,1\}\) then this is automatic, since only elements of this form are put into \(C_1\) at later stages.
Suppose \( \Phi_c(h) \) is of the form \( 1 \) \( \forall \) \( g \) for some \( g \in \mathcal{A} - \mathcal{A}_{1,t} \) and \( y \in \{0, 1\} \). Then \( (1 - y)^g \) was put into \( \mathcal{A}_{1,t+1} \) at stage \( s + 1 \), if not earlier. By construction, this ensures that all elements \( x^f \) entering \( \mathcal{A}_1 \) at a later stage \( t \geq s + 1 \) satisfy \( f \neq g \):

- If \( x^f \) enters \( \mathcal{A}_{1,t+1} \) at \( t = 2i + 1 \) then \( x^f = (1 - y)^g \) for some \( g \in \mathcal{A} - \mathcal{A}_{1,t} \) and \( y \in \{0, 1\} \). In particular \( f \neq g \) since \( g \in \mathcal{A}_{1,t} \).
- If \( x^f \) enters \( \mathcal{A}_{1,t+1} \) at \( t = 2i + 2 \) then \( f \in \mathcal{A} - \mathcal{A}_{1,t} \), so again \( f \neq g \).

Thus \( R^t_e \) is satisfied. The verification of \( R^t_1 \) at stage \( 2e + 2 \) is again symmetric.

**Lemma 2.2.** Let \( \mathcal{A} \) and \( \mathcal{B} \) be mass problems satisfying the condition

\[
\forall \mathcal{C} \subseteq \mathcal{A} \text{ finite} \left( \mathcal{B} \times \mathcal{C} \not\geq \text{M} \mathcal{A} \right).
\]

Then there exists an antichain \( \mathcal{E}_a, \alpha < 2^{\mathcal{A}_a} \), of mass problems such that \( \mathcal{E}_a \geq \text{M} \mathcal{A} \) for every \( \alpha \) and such that the elements \( \mathcal{B} \times \mathcal{E}_a \) are also pairwise \( \text{M} \)-incomparable.

**Proof.** We construct an antichain of size \( 2^{\omega_1} \) as in Sacks’ construction of such an antichain in the Turing degrees [11], [7, p. 462] by constructing a tree of the same as in Sacks’ construction. As a result, we obtain for every \( \mathcal{C} \), and the way in which the strategies are put together on a tree is as in Lemma 2.1, and the way in which the strategies are put together on a tree is the same as in Sacks’ construction. As a result, we obtain for every path \( \alpha \in \{0, 1\}^\omega \) a set \( \mathcal{E}_a = \bigcup_{\alpha \in \{0, 1\}^\omega} \mathcal{E}_a \) such that for every \( e \) and \( \beta \neq \alpha \) there is \( f \in \mathcal{E}_a \) such that \( \Phi_\tau(f) \notin \mathcal{B} \times \mathcal{E}_\beta \). So the sets \( \mathcal{B} \times \mathcal{E}_a, \alpha \in \{0, 1\}^\omega \), are pairwise \( \text{M} \)-incomparable.

**Lemma 2.3.** Let \( \mathcal{A} \) and \( \mathcal{B} \) be mass problems satisfying the condition

\[
\forall \mathcal{C} \subseteq \mathcal{A} \text{ finite} \left( \mathcal{B} \times \mathcal{C} \not\geq \text{M} \mathcal{A} \right).
\]

Then there exists an antichain \( \mathcal{E}_a, \alpha < 2^{\mathcal{A}_a} \), of mass problems such that \( \mathcal{E}_a \geq \text{M} \mathcal{A} \) for every \( \alpha \) and such that the elements \( \mathcal{B} \times \mathcal{E}_a \) are also pairwise \( \text{M} \)-incomparable. In particular, none of the \( \mathcal{E}_a \) is above \( \mathcal{B} \).

**Proof.** Start with the antichain \( \mathcal{E}_a, \alpha \in \{0, 1\}^\omega \) from Lemma 2.2. If we knew that for every \( \alpha \) there would be an \( f \in \mathcal{E}_a \) such that \( f \) does not compute an element from any \( \mathcal{E}_\beta \) with \( \beta \neq \alpha \) then we could simply argue as in the original argument of Platek [9] showing that \( \mathcal{A} \) has a big antichain, by taking \( 2^{\mathcal{A}_a} \) suitable combinations. But since we may not have this property we see ourselves forced to do something extra. For every \( I \subseteq \{0, 1\}^\omega \) define

\[
\mathcal{E}_I = \prod_{I \in \mathcal{E}_a} \mathcal{E}_a = \{ \alpha \oplus f: \alpha \in I \land f \in \mathcal{E}_a \}
\]

Note that we use the indices explicitly to create a sort of disjoint union of the possibly continuum many \( \mathcal{E}_a \). This generalization of the meet operator to larger cardinalities than \( \omega \) is no longer a natural meet operator. e.g., since the indices can be noncomputable elements of \( 2^{\omega} \) we lose the property that \( \mathcal{E}_a \geq \text{M} \prod_{\beta \in \mathcal{B}} \mathcal{E}_\beta \), even if \( \alpha \in I \) but this will not concern us.

We want to construct a perfect set of indices \( I \subseteq \{0, 1\}^\omega \) such that

\[
(\forall \alpha, \beta \in I)(\forall f \in \mathcal{E}_a)(\forall g \in \mathcal{E}_\beta) [\alpha \neq \beta \rightarrow \alpha \oplus f \not\parallel \beta \oplus g].
\]
The reason that it is possible to construct such a set of indices is that every $\mathcal{C}_\alpha$ is countable, and if $f \in \mathcal{C}_\alpha$ then $f$ in its totality is put into $\mathcal{C}_\alpha$ at some finite stage. We construct $\mathcal{T}$ as the set of paths in a (noncomputable) tree $T \subseteq 2^{<\omega}$.

Construction of $T$. Let $\mathcal{F}_\sigma, \sigma \in 2^{<\omega}$, refer to the finite approximations of the $\mathcal{C}_\alpha$ from the proof of Lemma 2.2. At stage $s$ of the construction we have defined $T(\sigma) \subseteq 2^{<\omega}$ for all $\sigma \in 2^{<\omega}$ of length $< s$. At stage $s$, for every $\sigma \neq \tau$ of length $s = e$ we guarantee

\[(\forall \alpha \in T(\sigma))(\forall \beta \in T(\tau))(\forall f \in \mathcal{F}_\alpha)(\forall g \in \mathcal{F}_\beta) [\Phi_e(\alpha \uplus f) \neq \beta \uplus g \land \Phi_e(\beta \uplus g) \neq \alpha \uplus f].\]

This can be realized in a standard finite extension construction à la Sacks, because the sets $\mathcal{F}_\alpha$ and $\mathcal{F}_\beta$ are finite. Given $f$ and $g$, the basic strategy for constructing $\alpha$ and $\beta$ with $\alpha \uplus f \uplus |_T \beta \uplus g$ is the same as in the Kleene–Post construction of two incomparable sets. This concludes the construction of $T$.

The construction of $T$ guarantees that its set of paths $\mathcal{T}$ satisfies (4): Given $\alpha \neq \beta$ in $\mathcal{T}$ and $f \in \mathcal{C}_\alpha, g \in \mathcal{C}_\beta$, the construction guarantees that $\Phi_e(\alpha \uplus f) \neq \beta \uplus g$ and $\Phi_e(\beta \uplus g) \neq \alpha \uplus f$ for all $e$ larger than the point in $T$ where $\alpha$ and $\beta$ split and larger than the stage where $f$ has entered $\mathcal{C}_\alpha$ and $g$ has entered $\mathcal{C}_\beta$. Since we have this for almost every $e$, by padding we have $\alpha \uplus f \uplus |_T \beta \uplus g$.

To finish the proof of the lemma, consider any family $\mathcal{I}$ of cardinality $2^{2^{\omega}}$ of pairwise incomparable subsets of $\mathcal{T}$ (cf. Proposition 3.1 below). If $I$ and $J$ are incomparable subsets of $\mathcal{T}$ then by (4) we have that $\mathcal{F}_I \upharpoonright_M \mathcal{F}_J$. But then, since for every $\alpha$ we have $\mathcal{E}_\alpha \upharpoonright_M B$, we also have $B \times \mathcal{F}_I \upharpoonright_M B \times \mathcal{F}_J$. Note that $\mathcal{E}_I \upharpoonright_M B$ because $\mathcal{E}_\alpha \subseteq B \times \mathcal{E}_I.$ So the sets $B \times \mathcal{F}_I, I \in \mathcal{I}$, form an antichain of cardinality $2^{2^{\omega}}$.

We note that one can prove the following variant of Lemma 2.1, with a weaker hypothesis and a weaker conclusion, and with a similar proof. A mass problem has finite degree if its $M$-degree contains a finite mass problem.

**Proposition 2.4.** Let $A$ be a mass problem that is not of finite degree, and let $B$ be any mass problem such that $B \upharpoonright_M A$. Then there exists a pair $\mathcal{E}_\alpha, \mathcal{E}_\beta$ of $M$-incomparable mass problems above $A$ such that neither of them is above $B$.

An $M$-degree is a degree of solvability if it contains a singleton mass problem. A mass problem is called nonsolvable if its $M$-degree is not a degree of solvability. For every degree of solvability $S$ there is a unique minimal $M$-degree $> S$ that is denoted by $S'$ (cf. Medvedev [4]). If $S = \deg_M(\{f\})$ then $S'$ is the degree of the mass problem

\[(5) \quad \{f\}' = \{n \in \omega : f <_T g \land \Phi_n(g) = f\}.
\]

(Note however that $S'$ has little to do with the Turing jump.) Dyment [2] proved that the degrees of solvability are precisely characterized by the existence of such an $S'$. In particular the Turing degrees form a first-order definable substructure of $\mathfrak{M}$. The empty intervals in $\mathfrak{M}$ are characterized by the following theorem. In view of what follows, it will be instructive to look at a proof of it.

**Theorem 2.5 (Dyment [2]).** For Medvedev degrees $A$ and $B$ with $A \upharpoonright_M B$ it holds that $(A, B) = \emptyset$ if and only if there is a degree of solvability $S$ such that $A \equiv_M B \times S$, $B \upharpoonright_M S$, and $B \leq_M S'$. 

Lemma 2.1 produces the M-incomparable sets if

\{ C \} \ni f \quad \text{such that} \quad \Psi(f) \not\in M \quad \text{and} \quad \Psi(g) \not\in M \quad \text{for otherwise we would have} \quad \Psi(f) \not\in M \quad \text{and} \quad \Psi(g) \not\in M \quad \text{by emptiness of the interval, and in particular} \quad \Psi(f) \not\in M \quad \text{and} \quad \Psi(g) \not\in M.

\begin{align*}
\{ f \}' \times \{ g \}' & \quad \text{if} \quad C \ni f \quad \text{and} \quad C \ni g \quad \text{and} \quad C \ni C \quad \text{since there is no other possibility for} \quad B \times \{ f \}. \\
\{ f \} \times \{ g \}' & \quad \text{if} \quad C \nmid f \quad \text{or} \quad C \nmid g \quad \text{or} \quad C \nmid C \quad \text{then empty.} \\
\{ g \} \times \{ f \}' & \quad \text{if} \quad C \nmid f \quad \text{and} \quad C \nmid g \quad \text{then} \quad C \nmid C \quad \text{if} \quad C \nmid C \quad \text{then empty.} \\
\{ f \} \times \{ g \} & \quad \text{if} \quad C \ni f \quad \text{and} \quad C \ni g \quad \text{then} \quad C \ni C \quad \text{if} \quad C \ni C \quad \text{then empty.}
\end{align*}

\begin{align*}
\{ f \}' \times \{ g \}' & \quad \text{if} \quad C \ni f \quad \text{and} \quad C \ni g \quad \text{and} \quad C \ni C \quad \text{then empty.} \\
\{ f \} \times \{ g \}' & \quad \text{if} \quad C \nmid f \quad \text{or} \quad C \nmid g \quad \text{or} \quad C \nmid C \quad \text{then empty.} \\
\{ g \} \times \{ f \}' & \quad \text{if} \quad C \nmid f \quad \text{and} \quad C \nmid g \quad \text{then empty.} \\
\{ f \} \times \{ g \} & \quad \text{if} \quad C \nmid f \quad \text{and} \quad C \nmid g \quad \text{then empty.}
\end{align*}

Figure 1. An interval with exactly two intermediate elements.

Lemma 2.6. Let \( n \geq 1 \) and let \( f_1, \ldots, f_n \in \omega^\omega \) be T-incomparable. Suppose that \( C \ni f_1, \ldots, f_n \) and \( C \nmid \{ f_i \}' \times \{ f_j \} : j \neq i \). Then \( C \nmid \{ f_i \} \).

Proof. Let \( C \) satisfy the hypotheses of the lemma. By \( C \ni \{ f_1, \ldots, f_n \} \) we have that \( C \) is included in the union of the Turing-upper cones of the \( f_i, \) \( 1 \leq i \leq n. \) If \( C \) did not contain any element of degree \( \deg_T(f_i) \) then we would have \( \{ f_i \}' \times \{ f_j \} : j \neq i \) \( \nmid \{ f_i \} \) as follows. Suppose that \( C \ni \{ f_1, \ldots, f_n \} \) via \( \Psi \). If \( \Psi \) sends an element \( h \in C \) to some \( f_i, j \neq i \) just let that happen, but if it sends \( h \) to \( f_i \) then instead output \( m'h \), where \( m \) is an index of \( \Psi \). In the latter case we have \( m'h \in \{ f_i \}' \). We can recognize these distinctions effectively because \( \{ f_1, \ldots, f_n \} \) is finite, so we can separate its elements by finite initial segments. This proves that \( C \) contains an element of degree \( \deg_T(f_i) \) and consequently \( C \nmid \{ f_i \} \) for some intermediate elements.

Proposition 2.7. There are nonempty intervals in \( \mathcal{M} \) that contain exactly two intermediate elements.

Proof. Let \( f \) and \( g \) be T-incomparable and define \( \mathcal{A} = \{ f, g \}, \mathcal{B} = \{ f \}' \times \{ g \}' \). We then have the situation as depicted in Figure 1. Note that \( \{ f \} \times \{ g \}' \) and \( \{ g \} \times \{ f \}' \) are indeed M-incomparable. By Theorem 2.5 the two intervals \( \{ f \} \times \{ g \}' \) and \( \{ f \} \times \{ g \}' \) on the left side of the picture are empty, and by symmetry the same holds for the two intervals on the right side.
Now suppose that
\[(6) \quad \{f, g\} \leq_M \mathcal{C} \leq_M \{f\}' \times \{g\}' \]
and that \(\{f\} \times \{g\}' \not\leq_M \mathcal{C}\). By Lemma 2.6 we then have \(\mathcal{C} \leq_M \{g\}\). But then, since by (6) we also have \(\mathcal{C} \leq_M \{f\}'\), we have \(\mathcal{C} \leq_M \{g\} \times \{f\}'\). Thus if \(\mathcal{C} \in \{\mathcal{A}, \mathcal{B}\}\) is not above \(\{f\} \times \{g\}'\) then it is below \(\{g\} \times \{f\}'\). Since all intervals depicted in Figure 1 are empty, it follows that there are only the four possibilities for \(\mathcal{C}\).

Since every interval in \(\mathcal{M}\) is a lattice, we see that the interval of Figure 1 is really isomorphic, as a lattice, to the Boolean algebra \(2^2\). Proposition 2.7 can be generalized to obtain finite intervals of size \(2^n\) as follows:

**Theorem 2.8.** Let \(\mathcal{B}\) be any mass problem. Let \(n \geq 1\) and let \(f_1, \ldots, f_n \in \omega^\omega\) be \(T\)-incomparable such that \(\{f_i\} \not\leq_M \mathcal{B}\) for every \(i\). Then the interval
\[
[\mathcal{B} \times \{f_1, \ldots, f_n\}, \mathcal{B} \times \{f_1\}' \times \ldots \times \{f_n\}']
\]
is isomorphic to the Boolean algebra \(2^n\).

**Proof.** For \(I \in 2^n\) define
\[
F(I) = \mathcal{B} \times \prod_{i \in I} \{f_i\}' \times \{f_i : i \notin I\}.
\]
Then clearly \(F(I) \leq_M F(J)\) whenever \(I \subseteq J\). Suppose that \(I \neq J\), say \(j \in J - I\). Then in \(F(I)\) the factor \(\{f_j\}\) occurs. But \(\{f_j\}\) is neither above \(\mathcal{B}\) nor above \(\{f_i\}'\) nor above \(\{f_i : i \neq j\}\), so \(F(I) \not\leq_M F(J)\). So \(F\) is an order-preserving injection.

We verify that \(F\) is onto. Suppose that \(\mathcal{C} \in [F(0), F(n)]\). We prove that \(\mathcal{C}\) is of the form \(F(I)\) for some \(I \subseteq n\). Let \(I\) be a maximal subset of \(n\) such that \(\mathcal{C} \geq_M F(I)\).

Note that such \(I\) exists since \(\mathcal{C} \equiv_M F(\emptyset)\). Suppose that \(i \notin I\) and that \(\mathcal{C}\) contains no element of degree \(\deg_T(f_i)\). Then similar argumentation as in Lemma 2.6 (just adding \(\mathcal{B}\) to the argument) shows that \(\mathcal{C} \equiv_M F(I \cup \{i\})\), contradicting the maximality of \(I\). So \(\mathcal{C}\) contains an element of degree \(\deg_T(f_i)\), and hence \(\mathcal{C} \leq_M \{f_i\}\). Since we have this for every \(i \notin I\) we have \(\mathcal{C} \leq_M \{f_i : i \notin I\}\). Since we also have \(\mathcal{C} \leq_M \mathcal{B} \times \prod_{i \in I} \{f_i\}'\) we have \(\mathcal{C} \leq_M F(I)\). Hence \(\mathcal{C} \equiv_M F(I)\).

We have proved that the interval is order-isomorphic to \(2^n\). But then it follows automatically that it is isomorphic to \(2^n\) as a lattice, since closing the elements \(F(I)\) under \(\times\) and \(+\) cannot add any new elements because \(F\) is onto. (It was already clear from the definition that the \(F(I)\) are closed under \(\times\).) Finally, since the interval is lattice-isomorphic to \(2^n\), it follows that in fact it is a Boolean algebra itself.

Platek [9] proved that \(\mathcal{M}\) has the (for a collection of sets of reals maximal possible) cardinality \(2^{2^{\aleph_0}}\) by showing that \(\mathcal{M}\) has antichains of that cardinality. (The result was noted independently by Elisabeth Jockusch and John Stillwell.) We now show that every interval in \(\mathcal{M}\) is either of cardinality \(2^n\) for some \(n \geq 1\) or of cardinality \(2^{2^{\aleph_0}}\).

In particular, Theorem 2.8 is the only way to generate finite intervals. We will use the following lemma from [15].

**Lemma 2.9. [15, Lemma 8.3]** For any singleton mass problem \(\mathcal{S}\), if \(\mathcal{B} \not\equiv_M \mathcal{S}'\) then \(\mathcal{S}'\) and \(\mathcal{B}\) satisfy condition (1) from Lemma 2.3.

**Theorem 2.10.** Let \([A, B]\) be an interval in \(\mathcal{M}\) with \(A <_M B\). Then either \([A, B]\) is isomorphic to the Boolean algebra \(2^n\) for some \(n \geq 1\), or \([A, B]\) contains an antichain of size \(2^{2^{\aleph_0}}\).
Proof. Let \( \mathcal{A} \) and \( \mathcal{B} \) be mass problems of degree \( A \) and \( B \), respectively. If \( \mathcal{A} \) and \( \mathcal{B} \) satisfy condition (1) from Lemma 2.3 then the lemma immediately gives an antichain of size \( 2^{\aleph_0} \) between \( \mathcal{A} \) and \( \mathcal{B} \). Suppose next that \( \mathcal{A} \) and \( \mathcal{B} \) do not satisfy condition (1): Let \( \mathcal{C} \subseteq \mathcal{A} \) be finite such that \( \mathcal{B} \times \mathcal{C} \leq \mathcal{M} \mathcal{A} \). Since also \( \mathcal{A} \leq \mathcal{M} \mathcal{B} \times \mathcal{C} \) we then have \( \mathcal{A} \equiv \mathcal{M} \mathcal{B} \times \mathcal{C} \). Since \( \mathcal{C} \) is finite we can separate its elements by finite initial segments and hence it holds that
\[
\mathcal{B} \times \mathcal{C} \equiv \mathcal{M} \mathcal{B} \times \{ f \in \mathcal{C} : \exists \mathcal{B} \ ( f ) \} \leq \mathcal{M} \mathcal{B} \wedge f \text{ is of minimal T-degree in } \mathcal{C}.
\]
so we may assume without loss of generality that the elements of \( \mathcal{C} \) are pairwise T-incomparable and satisfy \( \{ f \} \not\leq \mathcal{M} \mathcal{B} \).

First note that \( \mathcal{C} \) is nonempty since otherwise \( \mathcal{B} \equiv \mathcal{M} \mathcal{B} \times \mathcal{C} \leq \mathcal{M} \mathcal{A} \), but we have \( \mathcal{A} \leq \mathcal{M} \mathcal{B} \) by assumption.

Suppose that \( \mathcal{C} = \{ f_1, \ldots, f_n \} \), \( n \geq 1 \), so that \( \mathcal{A} \equiv \mathcal{M} \mathcal{B} \times \{ f_1, \ldots, f_n \} \). If \( \mathcal{B} \leq \mathcal{M} \{ f_1 \} \) then \( \mathcal{B} \equiv \mathcal{M} \mathcal{B} \times \{ f_1 \} \), so by Theorem 2.8 \( [\mathcal{A}, \mathcal{B}] \) is isomorphic to \( 2^n \).

If \( \mathcal{B} \not\equiv \mathcal{M} \{ f_1 \} \) then there is an i such that \( \mathcal{B} \not\equiv \mathcal{M} \{ f_i \} \). We now apply Lemma 2.3 to \( \{ f_i \} \) and \( \mathcal{B} \). This is possible because \( \{ f_i \} \) and \( \mathcal{B} \) satisfy condition (1) from Lemma 2.3 by Lemma 2.9. Lemma 2.3 now produces an antichain of elements \( \mathcal{B} \times \mathcal{C}_\alpha \) with \( \mathcal{C}_\alpha \not\equiv \mathcal{M} \{ f_i \} \). The elements of the antichain are clearly below \( \mathcal{B} \), and they are also above \( \mathcal{A} \) since \( \mathcal{C}_\alpha \not\equiv \mathcal{M} \{ f_i \} \). So we have again an antichain of size \( 2^{\aleph_0} \) in the interval \( (\mathcal{A}, \mathcal{B}) \).

Corollary 2.11 (Sorbi and Terwijn [15]). If \( [A, B] \neq \emptyset \) then there is a pair of incomparable degrees in \( [A, B] \).

In [15] Corollary 2.11 was used to show that the linearity axiom
\[
(p \rightarrow q) \lor (q \rightarrow p)
\]
is not in any of the theories Th(\( \mathcal{M}/\mathcal{A} \)) for \( \mathcal{A} \succ \mathcal{M} 0^* \), where Th(\( \mathcal{M}/\mathcal{A} \)) is the set of all propositional formulas that are valid on the Brouwer algebra \( \mathcal{M}/\mathcal{A} \).

Note that there are both \( 2^{2^{\aleph_0}} \) examples of finite and of infinite intervals in \( \mathcal{M} \). For the first, note that if \( \mathcal{B} \) is upwards closed under \( \leq_T \) and \( f \not\leq \mathcal{B} \) then by Theorem 2.8 we can construct a finite set with the pair \( (\mathcal{B}, f) \). Now as in Platek’s argument, taking an antichain of size \( 2^{\aleph_0} \) in the Turing degrees we see that there are \( 2^{\aleph_0} \) such pairs. all defining different finite intervals.

To see that there are also \( 2^{2^{\aleph_0}} \) infinite intervals, note that by the proof of Theorem 2.10 it suffices to show that there are \( 2^{2^{\aleph_0}} \) pairs \( (\mathcal{A}, \mathcal{B}) \) (with all the \( \mathcal{A} \)'s of different M-degree) satisfying condition (1) from Lemma 2.3. But this is easy to see, again using the antichain from above.

§3. Notes about chains and antichains in \( \mathcal{P}(\kappa) \). As a preparation for the next section we collect some notes about chains and antichains in \( ^2 \kappa \), for an arbitrary cardinal \( \kappa \). We claim no originality, but include two simple proofs for later reference. Our set-theoretic notation follows Kunen [3]. Note however that by an antichain we just mean a set of pairwise incomparable elements, whereas Kunen uses a stronger notion (with “incompatible” instead of “incomparable”). A chain in \( \mathcal{P}(\kappa) \) is any family of subsets of \( \kappa \) that is strictly linearly ordered by \( \subseteq \). In Sections 3 and 4 to avoid confusion with cardinal exponentiation, we use \( ^2 \kappa \) for the set of functions
from κ to 2 and 2κ for the cardinality of this set. Similarly, 2^{<κ} is the cardinality of 
\(<^κ2 = \bigcup_{κ<κ}2^κ.

**Proposition 3.1.** Let κ be any cardinal. Then the partial order \((\mathcal{P}(κ), ⊆)\) has an antichain of size 2^κ.

**Proof.** By explicit construction. Build a tree of \(C_κ \subseteq κ, X ∈ ^κ2\), in κ stages as follows. Start with \(C_0 = ∅\). For any stage \(α < κ\), pick two fresh (i.e., not previously used in the construction) elements of κ, and for any \(σ ∈ ^κ2\) of length \(α\), put one fresh element in \(C_σ\) and the other in \(C_{σ + 1}\). At limit stages \(α\) take unions. That is, let \(C_σ = \bigcup_{τ ∈ σ} C_τ\) for any \(σ ∈ ^κ2\) of length \(α\). For every \(X ∈ ^κ2\) let \(C_X = \bigcup_{σ < κ} C_X^{<κ}\).

End of construction.

Clearly, if \(X ≠ X′\) then \(C_X | C_X′\) (look at the first α where \(X\) and \(X′\) differ), so the \(C_X ⊆ κ\) form an antichain of size 2^κ.

For antichains we do not need any special properties of κ. For chains the situation is more complicated, but we have the following result.

**Proposition 3.2.** Let κ be any cardinal with 2^{<κ} = κ. Then the partial order \((\mathcal{P}(κ), ⊆)\) has a chain of size 2^κ.

**Proof.** This is a generalization of the fact that \(\mathcal{P}(ω)\) has chains of size 2^ω. We view \(\mathcal{P}(κ)\) as the set of paths in the tree ^κ2. Let \(<_L\) denote the Kleene–Brouwer ordering on \(^κ2 \cup \mathcal{P}(κ)\): for strings \(σ\) and \(τ\) of length \(≤ κ\), \(σ <_L τ\) if either \(σ ⊆ τ\) or there is an \(α < κ\) such that \(σ(α) < τ(α)\) and \(∀γ < α[σ(γ) = τ(γ)]\), i.e., \(σ\) is either an initial of \(τ\) or branches off to the left of \(τ\) in the tree ^κ2. Now every \(X ∈ ^κ2\) has an associated “Dedekind cut”

\[
\text{Cut}(X) = \{σ ∈ ^κ2: σ <_L X\}.
\]

By 2^{<κ} = κ, every cut corresponds to a subset of κ, and we have that \(X <_L Y\) implies that \(\text{Cut}(X) \subseteq \text{Cut}(Y)\). So under this assumption the cuts form a chain of size 2^κ. ⊣

Note that the chains in Proposition 3.2 cannot be well-ordered, since well-ordered chains in \(\mathcal{P}(κ)\) have size at most κ (since every next element of the chain has to add a new element).

In Section 4 we will be interested in the case \(κ = 2^ω\), the Medvedev lattice being a collection of sets of reals. The fact that for \(κ = 2^ω\) the condition 2^{<κ} = κ of Proposition 3.2 is independent of the standard set-theoretic framework of ZFC (since it is true under CH and false e.g., when \(2^ω = ω_2\) and \(2^{ω_2} = ω_3\)) suggests that the existence of big chains in \(\mathcal{P}(2^ω)\) might also be independent. Perhaps surprisingly, it seems that this problem is open.

**Problem 3.3.** Settle the independence of ZFC of the existence of chains of size 2^{ω_0} in \(\mathcal{P}(2^ω)\).

§4. Chains in \(M\). Since \(M\) is defined by factoring out sets of reals modulo the reduction relation \(≤_M\), a priori its maximal possible cardinality is 2^{ω_0}. In Section 2 we have seen that \(M\) has indeed cardinality 2^{ω_0}, and in fact that every infinite interval contains an antichain of this cardinality. In this section we consider the height of intervals, that is, we discuss chains. First we note that every M-degree different from the top degree is as large as set-theoretically possible:
Proposition 4.1. For every nonempty mass problem $\mathcal{T} \subseteq \omega^\omega$ we have that $|\operatorname{deg}_M(\mathcal{T})| = 2^{2^{\aleph_0}}$.

Proof. This follows by simple counting. For every $\mathcal{X} \subseteq \omega^\omega$ define

$$\mathcal{A}_\mathcal{X} = \{ f \oplus g : f \in \mathcal{T} \land g \in \mathcal{X} \cup \{0^\omega\}\},$$

where $0^\omega$ is the all zero sequence. Then $\mathcal{A}_\mathcal{X} \leq_M \mathcal{T}$ since for all $f \in \mathcal{T}$, $f \oplus 0^\omega \in \mathcal{A}_\mathcal{X}$, and $\mathcal{T} \leq_M \mathcal{A}_\mathcal{X}$ since for all $h \in \mathcal{A}_\mathcal{X}$, $h_0 = f \in \mathcal{T}$, where $h_0$ is the unique component such that $h = h_0 \oplus h_1$. So $\mathcal{A}_\mathcal{X} \equiv_M \mathcal{T}$ for every $\mathcal{X}$, hence the result follows. \qed

We have seen in Section 3 that whether or not $\mathcal{P}(2^n)$ has chains of size $2^{2^{\aleph_0}}$ may depend on set-theoretic properties of $2^n$. The same holds for $\mathcal{M}$. Next we show that it is at least consistent with ZFC that $\mathcal{M}$ has chains of the size of its own cardinality.

Theorem 4.2. CH implies that $\mathcal{M}$ has a chain of size $2^{2^{\aleph_0}}$.

Proof. We build on the proof of Proposition 3.2. Note that under CH we have $2^{<2^n} = 2^{<\kappa \cdot n} = 2^n$, so the condition of Proposition 3.2 is satisfied for $\kappa = 2^n$. Let $\{f\alpha : \alpha < 2^n\}$ be a set of pairwise Turing incomparable elements of $\omega^\omega$, which exists by a result of Sacks [11]. Now by CH the sets $\text{Cut}(X)$ defined in the proof of Proposition 3.2 correspond with subsets of $\omega^\omega$, hence also with subsets of $\{f\alpha : \alpha < 2^n\}$. Call this correspondence $F$, so that $\text{Cut}(X)$ corresponds to $F(\text{Cut}(X))$. Again we have $X <_L Y$ implies that $\text{Cut}(X) \subseteq \text{Cut}(Y)$, which in turn implies that $F(\text{Cut}(X)) \subseteq F(\text{Cut}(Y))$. But then $F(\text{Cut}(Y)) \leq_M F(\text{Cut}(X))$ because any $f\alpha$ in $F(\text{Cut}(Y)) - F(\text{Cut}(X))$ cannot compute an element of $F(\text{Cut}(X))$. \qed

From the proof of Theorem 4.2 we see that the conditions for the existence of big chains in $\mathcal{P}(2^n)$ and in $\mathcal{M}$ are exactly the same.

In Theorem 2.10 we saw that every interval in $\mathcal{M}$ is either small (isomorphic to a finite Boolean algebra) or contains a big antichain. We now show that it is consistent that the interval also has a big chain whenever it has a big antichain.

Theorem 4.3. Let $[A, B]$ be an interval in $\mathcal{M}$ with $A <_M B$. Then either $[A, B]$ is isomorphic to the Boolean algebra $2^n$ for some $n \geq 1$, or $[A, B]$ contains an antichain of size $2^{2^{\aleph_0}}$. In the latter case, assuming CH, it also contains a chain of size $2^{2^{\aleph_0}}$.

Proof. By Theorem 2.10 and its proof we only have to show how to obtain a big chain from the big antichain we constructed in Lemma 2.3. Recall the sets $\mathcal{C}_\alpha$ and $\mathcal{C}_I$ from the proof of Lemma 2.3, and also the special set of indices $\mathcal{F} \subseteq \omega^\omega$ defined there. $\mathcal{F}$ is of cardinality $2^{\aleph_0}$ and order-isomorphic to $2^n$, with the order inherited from $2^n$. Let $\leq_L$ be the Kleene–Brouwer ordering defined as in Proposition 3.2, but now on the tree $<_{\mathcal{F}} 2 \cup \mathcal{F}$. For every $I \in \mathcal{F}$ we have the associated set

$$\text{Cut}(I) = \{ \sigma \in <_{\mathcal{F}} 2 : \sigma \leq_L I \}.$$

By CH, $|<_{\mathcal{F}} 2| = 2^{<_{\mathcal{F}} 2} = 2^\omega = |\mathcal{F}|$, so we can associate with every $\text{Cut}(I)$ a subset $F(\text{Cut}(I))$ of $\mathcal{F}$. Now let

$$\mathcal{R}(I) = \{ \alpha \oplus f : \alpha \in F(\text{Cut}(I)) \land f \in \mathcal{C}_\alpha \}.$$

Clearly the cuts, and hence the $\mathcal{R}(I)$, form a monotone sequence, that is,

$$J \leq_L I \Rightarrow \text{Cut}(J) \subseteq \text{Cut}(I) \Rightarrow \mathcal{R}(J) \subseteq \mathcal{R}(I) \Rightarrow \mathcal{R}(I) \leq_M \mathcal{R}(J).$$

The sequence is strict because $J <_L I$ implies that there is an $\alpha \in F(\text{Cut}(I)) - F(\text{Cut}(J))$, and by the property (4) in the proof of Lemma 2.3 we then have that...
Thus we have \( \mathscr{E}(I) \not<_M \mathscr{E}(J) \) whenever \( J <_L I \). So the sets \( \mathscr{E}(I) \) form a chain in \( \mathcal{M} \) of cardinality \( |\mathcal{F} \mathcal{Z}| = 2^{2^{\omega_0}} \).

§5. Embeddings into \( \mathcal{M} \). Sorbi characterized the countable lattices that are embeddable into \( \mathcal{M} \) as follows:

**Theorem 5.1** (Sorbi [13, 14]). A countable distributive lattice with 0.1 is embeddable into \( \mathcal{M} \) (preserving 0 and 1) if and only if 0 is meet-irreducible and 1 is join-irreducible.

Sorbi proved Theorem 5.1 by embedding the (unique) countable dense Boolean algebra into \( \mathcal{M} \). Below we show that this embedding is optimal as far as cardinalities are concerned: Every Boolean algebra embeddable into \( \mathcal{M} \) must be countable. We first show that (the dual of) the large Boolean algebra \( \mathscr{B}(2^\omega) \) is embeddable into \( \mathcal{M} \) as an upper semilattice, i.e., preserving joins but not necessarily meets.

We recall the following definitions concerning 1-genericity. A computation \( \{e\}^\tau(x) \) is strongly undefined if \( \{e\}^\tau(x) \uparrow \) for every \( \tau \supseteq \sigma \). A set of strings \( D \subseteq 2^{<\omega} \) is dense along a set \( G \) if for every \( \sigma \subseteq G \) there is \( \tau \supseteq \sigma \) such that \( \tau \in D \). The set \( G \) meets \( D \) if there is \( \sigma \subseteq G \) such that \( \sigma \in D \). \( G \) is 1-generic if \( G \) meets every \( D \in \Sigma^0_1 \) that is dense along \( G \). For more background on 1-generic sets see e.g., Odifreddi [8].

We emphasize the difference between the following two notations: \( \sigma \subseteq G \) denotes that the finite string \( \sigma \) is an initial segment of the set \( G \), and \( \sigma \subseteq G \) denotes that \( \sigma \), seen as a finite set, is a subset of \( G \). \( |\sigma| \) denotes the length of the string \( \sigma \). \( f =^* g \) denotes that the functions \( f \) and \( g \) differ only on finitely many elements.

**Lemma 5.2.** Let \( G \) be 1-generic, \( e \in \omega \), and \( \sigma \subseteq G \).

(i) There exist \( x \) and \( \rho, \tau \) with \( \sigma \subseteq \rho \cup \tau \subseteq G \), and \( |\rho| = |\tau| \) such that either

- \( \tau(x) \neq \{e\}^\rho(x) \downarrow \), or
- \( \{e\}^\rho(x) \) is strongly undefined.

(ii) There exist \( x \) and \( \rho \) with \( \sigma \subseteq \rho \subseteq G \) such that either

- \( \tau(x) \neq \{e\}^\rho(x) \downarrow \), or
- \( \{e\}^\rho(x) \) is strongly undefined.

**Proof.** (i) Let \( \sigma \subseteq G \). Suppose the second case of (i) cannot be obtained, that is,

\[ \forall x \forall \rho, \sigma \subseteq \rho \subseteq G \exists \rho' \supseteq \rho \{e\}^\rho'(x) \downarrow. \]

Then one easily checks that the set

\[ \{\rho \cup \tau: \exists x (\sigma \subseteq \rho \land \{e\}^\rho(x) \downarrow)\} \]

is dense along \( G \). But then also the \( \Sigma^0_1 \) set

\[ D = \{\rho \cup \tau: \exists x (\sigma \subseteq \rho \land \tau(x) \neq \{e\}^\rho(x) \downarrow)\} \]

is dense along \( G \). By genericity \( G \) meets \( D \), i.e., \( G \cap n = \rho \cup \tau \) for some \( n \) and \( \rho \cup \tau \in D \), and we see that the first case of (i) obtains. (If \( |\rho| \neq |\tau| \) simply extend one to the length of the other with arbitrary bits.)

(ii) Suppose the second case of (ii) cannot be obtained, i.e., that (7) holds. Then the \( \Sigma^0_1 \) set

\[ D = \{\rho \cup \tau: \exists x (\sigma \subseteq \rho \cup \rho \cup \tau(x) \neq \{e\}^\rho(x) \downarrow)\} \]

is dense along \( G \), hence \( G \) meets \( D \). and \( \rho \) as in the first case of (ii) is found. \( \triangleright \)
LEMMA 5.3. There exist a noncomputable \( g \in 2^\omega \) and \( g_X \in 2^\omega \) (\( X \) ranging over \( 2^\omega \)), and a total computable functional \( \Psi \) such that for all \( X \) and \( Y \),

- \( g \not\in \tau X \),
- \( X \neq Y \implies g_X \upharpoonright \tau Y \),
- \( X \neq Y \land h_0 =^* g_X \land h_1 =^* g_Y \implies \Psi(h_0 \oplus h_1) =^* g \).

Proof. Note that this is an extension of the existence of an antichain of size \( 2^{\aleph_0} \) in the Turing degrees [11]. It can be realized by standard methods from computability theory, so we will leave some of the details of the proof to the reader. Let \( G \) be 1-generic. Below we imitate Sacks’ construction, which is a (noneffective) finite extension construction, but now we do it within the given set \( G \). 1-Genericity of \( G \) will guarantee that we will find the necessary extensions inside \( G \).

We construct a tree of finite strings \( G_x \), \( x \in 2^{\omega \omega} \), such that for the sets \( G_X = \bigcup_{x \in X} G_x \), with \( X \in 2^\omega \), we have that \( X \neq Y \implies G_X \upharpoonright \tau Y \) and

\[
X \neq Y \implies G_X \cup G_Y = G. \tag{8}
\]

Let \( 2^s \) denote the strings of length \( s \). At stage \( s \) we have defined finite strings \( G_x \) for every \( x \in 2^s \), all of equal length. We satisfy the following requirements: For every \( s \) and every pair \( x, y \in 2^s \), and for \( e = s \), we ensure that

- (i) \( Y \neq \{e\}^X \) for all \( X \nsubseteq G_x \) and \( Y \nsubseteq G_y \),
- (ii) \( G \neq \{e\}^X \) for all \( X \nsubseteq G_x \).

These requirements can be satisfied successively by choosing appropriate finite extensions of \( G_x \) and \( G_y \), using Lemma 5.2 (i) and (ii) for requirements (i) and (ii), respectively. To satisfy (8), if in case (i) \( G_x \) is extended to \( \rho \) and \( G_y \) to \( \tau \), then we extend all other \( G_z \), \( z \neq x, y \) to \( \rho \cup \tau \), and, in all other cases, if \( G_x \) is extended to \( \rho \) then extend all other \( G_y \), \( y \neq x \), with \( \rho' \), \( |\rho'| = |\rho| \), such that \( \rho \cup \rho' \nsubseteq G \). At the end of stage \( s \) we have thus \( 2^s \) finite strings \( \sigma \) of equal length and with \( \sigma \subseteq G \). To obtain a full tree, we split every \( \sigma \) by choosing two incomparable extensions. For the sake of (8) these extensions have to satisfy the constraint that the union of every two of them are an initial of \( G \). Clearly we can realize this since \( G \) is infinite. (Namely to split the \( 2^s \) strings we need \( 2^s \) different points \( x \) with \( G(x) = 1 \).) This gives \( 2^{s+1} \) finite strings of equal length for the next stage \( s+1 \).

In this way we obtain \( G \) and \( G_X \) satisfying the first two items of the lemma, as well as (8). Finally, by defining \( \Psi(h_0 \oplus h_1) = h_0 \cup h_1 \) we see that we also have the third item.

For any Boolean algebra \( \mathcal{B} \), let dual(\( \mathcal{B} \)) denote the dual of \( \mathcal{B} \).

THEOREM 5.4. There is an embedding of dual(\( \mathcal{P}(2^\omega) \)) into \( \mathcal{M} \) as an upper semilattice.

Proof. Let \( g \) and \( g_X \) be as in Lemma 5.3. Let Fin(\( g \)) be the set of all finite differences of \( g \). \( \sigma \oplus \text{Fin}(g) \) denotes the set \( \{ \sigma \oplus f : f \in \text{Fin}(g) \} \). Consider the mass problems

\[
\mathcal{A}_I = \bigcup_{\sigma \in 2^{\omega \omega}} \sigma 0^\omega \oplus \text{Fin}(g) \cup \bigcup_{\sigma \in 2^{\omega \omega}, X \in I} \sigma 1^\omega \oplus \text{Fin}(g_X)
\]

for every \( I \subseteq 2^\omega \). We claim that \( F : \text{dual}(\mathcal{P}(2^\omega))) \hookrightarrow \mathcal{M} \) defined by \( I \mapsto \text{deg}_M(\mathcal{A}_I) \) is an embedding of upper semilattices. Clearly \( I \subseteq J \) implies that \( F(J) \leq_M F(I) \), and we have \( F(J) <_M F(I) \) if the inclusion is strict because \( g_X \) can neither compute \( g \).
nor any other $g_Y$. We check that $F(I \cap J) \equiv_M F(I) + F(J)$. Clearly $\mathcal{A}_I, \mathcal{A}_J \leq_M \mathcal{A}_{I \cap J}$ via inclusion, hence $\mathcal{A}_I + \mathcal{A}_J \leq_M \mathcal{A}_{I \cap J}$. Conversely, $\mathcal{A}_{I \cap J} \leq_M \mathcal{A}_I + \mathcal{A}_J$.

Suppose $f_0 \oplus h_0 \in \mathcal{A}_I$ and $f_1 \oplus h_1 \in \mathcal{A}_J$. We effectively produce an element $f \oplus h \in \mathcal{A}_{I \cap J}$ as follows. At stage $s$ we define $f(s)$ and $h(s)$. The "earmarks" $f_0$ and $f_1$ function as a series of guesses as to whether $h_0$ and $h_1$ are in $\text{Fin}(g)$ or not. E.g., if $f_0(s) = 0$ we guess the answer is yes for $h_0$, and no otherwise. If one of $h_0$ and $h_1$ is in $\text{Fin}(g)$ we want to produce one of them (with a suitable label). If neither is in $\text{Fin}(g)$ and $h_0 = h_1$ we can produce $1^\omega \oplus h_0$ since this is in $\mathcal{A}_{I \cap J}$. If neither is in $\text{Fin}(g)$ and $h_0 \neq h_1$ then $\Psi(h_0 \oplus h_1)$ is an element of $\text{Fin}(g)$ by Lemma 5.3. The labels are needed because we cannot a priori distinguish between these cases.

Formally the construction is as follows:

If $f_0(s) = 0$ we put $f(s) = 0$ and $h(s) = h_0(s)$.
If $f_0(s) = 1$ and $f_1(s) = 0$ we put $f(s) = 0$ and $h(s) = h_1(s)$.
If $f_0(s) = f_1(s) = 1$ and $h_0|s = h_1|s$ put $f(s) = 1$ and $h(s) = h_0(s)$.
If $f_0(s) = f_1(s) = 1$ and $h_0|s \neq h_1|s$ put $f(s) = 0$ and $h(s) = \Psi(h_0 \oplus h_1)(s)$.

This concludes the construction. We check that $f \oplus h \in \mathcal{A}_{I \cap J}$:

If $h_0 \in \text{Fin}(g)$ then $f = *^0\omega$ and $h = *^0 h_0$.
If $h_0 \notin \text{Fin}(g)$ and $h_1 \in \text{Fin}(g)$ then $f = *^0\omega$ and $h = *^1 h_1$.
If $h_0, h_1 \notin \text{Fin}(g)$ and $h_0 = h_1$ then $f = *^1\omega$ and $h = *^1 h_0$.
If $h_0, h_1 \notin \text{Fin}(g)$ and $h_0 \neq h_1$ then $f = *^00\omega$ and $h = *^0 \Psi(h_0 \oplus h_1)$ by Lemma 5.3.

The next result shows that the Boolean algebra dual($\mathcal{P}(2^\omega)$) is not embeddable into $\mathfrak{B}$ as a lattice. Note that such an embedding would automatically be an embedding as a Boolean algebra.

**Theorem 5.5.** Suppose $\mathscr{B}$ is a Boolean algebra that is embeddable into $\mathfrak{B}$ as a lattice (i.e., preserving meets and joins). Then $\mathscr{B}$ is countable.

**Proof.** Suppose for a contradiction that $\mathscr{B}$ is uncountable and that $F : \mathscr{B} \hookrightarrow \mathcal{P}(2^\omega)$ defines an embedding of $\mathscr{B}$. i.e., that $X \mapsto \deg_M(F(X))$ is an embedding of $\mathscr{B}$ into $\mathfrak{B}$. By the Stone representation theorem we may think of $\mathscr{B}$ as an algebra of sets, so we denote the lattice operations in $\mathscr{B}$ by $\cap$ and $\cup$. Let $\emptyset$ be the bottom element of $\mathscr{B}$, and for $X \in \mathscr{B}$ let $\overline{X}$ denote the complement of $X$ in $\mathscr{B}$. By assumption we then have $F(X \cap Y) \equiv_M F(X) \times F(Y)$ and $F(X \cup Y) \equiv_M F(X) + F(Y)$ for all $X$ and $Y$ in $\mathscr{B}$. In particular we have for every $X \in \mathscr{B}$ that

$$F(X) \times F(\overline{X}) \leq_M F(\emptyset).$$

Because $\mathscr{B}$ is uncountable there are uncountably many inequalities of the form (9). Since there are only countably many computable functionals $\Phi$, there must be two different $X, Y \in \mathcal{B}$ such that $F(X) \times F(\overline{X}) \leq_M F(\emptyset)$ and $F(Y) \times F(\overline{Y}) \leq_M F(\emptyset)$ via the same $\Phi$, so that we have

$$F(\emptyset) \geq_M F(X) \times (F(\overline{X}) \cap F(\overline{Y})).$$

Since $X \neq Y$ we have that either $X \not\subseteq Y$ or $Y \not\subseteq X$. For definiteness say that $X \not\subseteq Y$. Since $F(\overline{X}) \cap F(\overline{Y}) \subseteq F(\overline{X}), F(\overline{Y})$ we also have

$$F(\overline{X}) \cap F(\overline{Y}) \geq_M F(\overline{X}) + F(\overline{Y}) \equiv_M F(\overline{X} \cup \overline{Y}).$$
Putting these together we obtain

\[ F(\emptyset) \geq_M F(X) \times (F(X) \cap F(\overline{Y})) \]
\[ \geq_M F(X) \times F(X \cup \overline{Y}) \]
\[ \equiv_M F(X \cap (X \cup \overline{Y})) \]
\[ \equiv_M F(X \cap \overline{Y}) \]
\[ \geq_M F(\emptyset). \]

Hence \( F(\emptyset) \equiv_M F(X \cap \overline{Y}) \), which is a contradiction because by \( X \nsubseteq Y \) it holds that \( X \cap \overline{Y} \neq \emptyset \).

§.6. The Muchnik lattice. There is a nonuniform variant of the Medvedev lattice, called the Muchnik lattice, that was introduced by Muchnik in [6]. This is the structure \( \mathcal{M}_w \) resulting from the reduction relation on mass problems defined by

\[ \mathcal{A} \leq_w \mathcal{B} \equiv (\forall f \in \mathcal{B}) (\exists g \in \mathcal{A}) [g \leq_T f]. \]

That is, every solution to the mass problem \( \mathcal{B} \) can compute a solution to the mass problem \( \mathcal{A} \), but maybe not in a uniform way. \( \mathcal{M}_w \) is a distributive lattice in the same way that \( \mathcal{M} \) is, with the same lattice operations and 0 and 1. An M-degree is a Muchnik degree if it contains a mass problem that is upwards closed under Turing reducibility \( \leq_T \). The Muchnik degrees of \( \mathcal{M} \) form a substructure that is isomorphic to \( \mathcal{M}_w \) as an upper semilattice (but not as a lattice), i.e., preserving joins but not meets, and also preserving the Brouwer algebra operation \( \rightarrow \), cf. Sorbi [13, Fact 5.7].

We check which of the results from the previous section hold also for \( \mathcal{M}_w \) instead of \( \mathcal{M} \), replacing \( \leq_M \) by \( \leq_w \). As we will see, because of the lack of uniformity much more is possible in \( \mathcal{M}_w \), making it a structure much closer to the Turing degrees. In particular we no longer have strong dichotomies as in Theorem 2.10.

**Example 6.1.** The three-element chain occurs as an interval of \( \mathcal{M}_w \). We can see this as follows: Let \( f \) and \( \emptyset \not\leq_T g \not\leq_T f \) be such that the Turing lower cone of \( f \) consists precisely of three elements:

\[ (\forall h \leq_T f \rightarrow h \text{ computable } \lor h \equiv_T g \lor h \equiv_T f). \]

Such \( f \) exists since Titgemeyer proved that the three-element chain is embeddable into the Turing degrees as an initial segment, cf. [7, p. 526]. (Eventually Lachlan and Lebeuf proved that every countable upper semilattice with least element is embeddable as an initial segment.) Now let \( \mathcal{B} = \{ h : h \not\leq_T f \} \) and \( \mathcal{A} = \mathcal{B} \times \{ g \} \).

We claim that \( (\mathcal{A}, \mathcal{B}) \) contains only one element, namely \( \mathcal{B} \times \{ f \} \). Suppose that \( \mathcal{C} \in (\mathcal{A}, \mathcal{B}) \). Then there exists \( h \in \mathcal{C} \) such that \( \{ h \} \not\leq_w \mathcal{B} \), hence \( h \not\leq_T f \), so either \( h \equiv_T g \) or \( h \equiv_T f \). If \( \mathcal{C} \) contains such an \( h \) with \( h \equiv_T g \), then \( \mathcal{C} \leq_w \mathcal{A} \times \{ g \} = \mathcal{A} \).

Otherwise, all \( h \in \mathcal{C} \) with \( \{ h \} \not\leq_w \mathcal{B} \) have \( h \equiv_T f \), so we have both \( \mathcal{C} \leq_w \mathcal{B} \times \{ f \} \) and \( \mathcal{B} \times \{ f \} \leq_w \mathcal{C} \).

From Example 6.1 we see that there are linear nonempty intervals in \( \mathcal{M}_w \). This shows in particular that Corollary 2.11 fails for \( \mathcal{M}_w \).

In the proof of Dyment’s Theorem 2.5 given in Section 2 we used Lemma 2.1, which fails for \( \mathcal{M}_w \) (because \( \mathcal{M}_w \) contains an infinite downward chain, cf. the proof of Lemma 6.2). Nevertheless, the theorem still holds for \( \mathcal{M}_w \). Instead of Lemma 2.1 one can use the following much easier result:
Lemma 6.2. Suppose that $\mathcal{A}$ and $\mathcal{B}$ satisfy
\begin{equation}
\forall C \subseteq \text{finite} \ (\mathcal{B} \times C \preceq \mathcal{A}).
\end{equation}
Then there exists $C \geq_w \mathcal{A}$ such that $C \not\preceq_w \mathcal{B}$ and $\mathcal{B} \times C \preceq_w \mathcal{A}$. If moreover $\mathcal{A} \preceq_w \mathcal{B}$ then the interval $(\mathcal{A}, \mathcal{B})$ is infinite.

Proof. Since from (10) it follows that $\mathcal{B} \preceq_w \mathcal{A}$, there is $f \in \mathcal{A}$ such that \{f\} $\geq_w \mathcal{B}$. Again by (10) we have that $\mathcal{B} \times \{f\} \not\preceq_w \mathcal{A}$, so we can take $C = \{f\}$.

If in addition $\mathcal{A} \preceq_w \mathcal{B}$ then we have $\mathcal{A} <_w \mathcal{B} \times \{f\} <_w \mathcal{B}$. Since $\mathcal{A}$ and $\mathcal{B} \times \{f\}$ also satisfy (10) we can by iteration of the first part of the lemma obtain an infinite downward chain in $(\mathcal{A}, \mathcal{B})$. $\dashv$

The proof of Theorem 2.5 for $\mathcal{M}_w$ is now exactly the same as the proof given above, replacing $\preceq_M$ by $\preceq_w$ and using Lemma 6.2 where previously Lemma 2.1 was used.

Theorem 2.8 still holds for $\mathcal{M}_w$, with the same proof, but as we have seen in Example 6.1 it is not the only way anymore to generate finite intervals. In Terwijn [16] the finite intervals of $\mathcal{M}_w$ are characterized as a certain proper subclass of the finite distributive lattices.

In contrast to Theorem 4.3, an interval in $\mathcal{M}_w$ can be infinite without containing a large antichain. In fact, in [16] it is proved that there are intervals in $\mathcal{M}_w$ with maximal antichains of every possible size. Similar results can be obtained for chains. Theorem 4.2 holds for $\mathcal{M}_w$, with the same proof, so the conditions for the existence of chains of size $2^{2^n}$ in $\mathcal{M}$ and in $\mathcal{M}_w$ are the same. The consistency of the existence of chains of this size also follows from Proposition 6.3 below.

Proposition 4.1 also holds for $\mathcal{M}_w$, with the same proof, so again every Muchnik degree is as large as set-theoretically possible. Theorem 5.5 does not hold for $\mathcal{M}_w$, as we can in fact embed the dual of $\mathcal{P}(2^n)$:

Proposition 6.3. dual($\mathcal{P}(2^n)$) is embeddable into $\mathcal{M}_w$ as a Boolean algebra.

Proof. This follows simply by noting that the embedding $F$ given in the proof of Theorem 5.4, that did not preserve meets for $\mathcal{M}$, does in fact preserve meets in $\mathcal{M}_w$. Note that we have $\mathcal{A} \times \mathcal{B} \equiv_w \mathcal{A} \cup \mathcal{B}$. For $\mathcal{M}$ we have $F(I \cup J) \preceq_M F(I) \times F(J)$ but not necessarily $F(I \cup J) \geq_M F(I) \times F(J)$. But we do have $F(I \cup J) \geq_w F(I) \times F(J)$, as is immediate from the definitions. $\dashv$

Acknowledgments. The author thanks Martin Goldstern, Jakob Kellner, and Andrea Sorbi for helpful discussions.
