We report on continued Swift X-ray monitoring observations of the Galactic center region following the detection of a bright X-ray flare (Atel #6456). A new 1 ks Swift/XRT pointing performed on 2014-09-10 (06:52 UT) reveals that the X-ray emission at the position of Sgr A\* and the magnetar SGR 1745-29 has returned to the pre-flare level.

From the new observation we measure an unabsorbed 2-10 keV X-ray flux of  $\sim 1\text{E-}11$  erg/cm<sup>2</sup>/s at the position of Sgr A\*/SGR 1745-29, which corresponds to a luminosity of  $\sim 8\text{E}34$  erg/s at a distance of 8 kpc. This is consistent with the pre-flare level, which is largely attributed to X-ray emission from the (slowly fading) magnetar. This suggests that Swift/XRT detected a short-lived X-ray flare and that there are no indications of sustained enhanced X-ray activity. The duration, peak flux and spectral shape of the 2014 flare look very similar to six previous X-ray flares detected from Sgr A\* by Swift/XRT (Degenaar et al. 2013, ApJ 769, 155).

XRT monitoring observations of the Galactic center region are ongoing and results are posted promptly at the [Swift Sgr A\\* Monitoring Campaign Website](#).
