Targeted labeling of an early-stage tumor spheroid in a chorioallantoic membrane model with upconversion nanoparticles†

In vivo detection of cancer at an early-stage, i.e. smaller than 2 mm, is a challenge in biomedicine. In this work target labeling of an early-stage tumor spheroid (~500 µm) is realized for the first time in a chick embryo chorioallantoic membrane (CAM) model with monoclonal antibody functionalized upconversion nanoparticles (UCNPs-mAb).

In clinical oncology the detection of early-stage cancer like carcinoma in situ and tumors smaller than 2 mm is of great importance for improving the cancer cure probability.1–3 Unfortunately, most of the present clinical imaging modalities like ultrasonic imaging, computed tomography (CT), and magnetic resonance imaging (MRI) are not sufficient for detecting the early-stage cancers because of their low resolution and/or poor sensitivity and/or specificity.4,5 Fluorescence imaging has recently regained increased attention for cancer diagnosis, because of the new developments in exogenous luminescent materials,6–14 such as rare earth ion doped upconversion nanoparticles (UCNPs) that can efficiently convert near infrared (NIR) light to visible and/or shorter wavelength NIR light. In comparison with traditional “down conversion” fluorescent markers that need ultra-violet or visible (UV-Vis) light for excitation, the UCNPs hold many advantages for biomedical imaging, such as minimized background fluorescence, and no photo bleaching.11–14 Furthermore, since UCNPs have a large surface area, bio-functionalized molecules like folic acid, peptides, photosensitizers, doxorubicin (DOX), and si-RNA can be easily conjugated for multifunctional labeling or therapy. Numerous research studies have been reported in this respect on both in vitro and in vivo tests utilizing UCNPs.15–25 For example, Zhou et al. achieved tri-mode imaging of upconversion luminescence, magnetic resonance and positron emission tomography (PET) in mouse utilizing fluorine-18-labeled Gd³⁺/Yb³⁺/Er³⁺ co-doped NaYF₄ UCNPs.23 However, these research studies are performed on the mice model in which the imaging is usually executed at a relatively late stage when tumors reach 4–6 mm. In vivo target detection of early stage cancer, i.e. smaller than 2 mm, remains a difficult task in biomedicine.

In this work, target labeling of an early-stage tumor spheroid (~500 µm) was realized for the first time in a chick embryo chorioallantoic membrane (CAM) model with monoclonal antibody functionalized upconversion nanoparticles (UCNPs-mAb). An early-stage tumor spheroid model was built first by transplanting an in vitro cultured 3 dimensional multicellular tumor spheroid (MCTS) of human breast cancer cells MCF-7 onto the chick embryo CAM. The chick embryo CAM is a well-established model which has already been widely used for cancer and angiogenesis research, drug delivery, immunology etc.26–34 Compared with the widely used mice model, the chick embryo CAM has unique advantages in cancer research, including (i) the chick embryo is a naturally immunodeficient system, and various heterogeneous tumor cells can be transplanted into the CAM without any species-specific restrictions, and (ii) since the chick embryo CAM is an extremely thin membrane layer (~200 µm) that usually lies at the top, it is very convenient to observe the motility process of the injected cancer cells or drug molecules under a microscope with little impact on the host. On top of that, the chick embryo model is simple...
(without animal manipulation), low cost, easy to maintain, and easily accessible. Since the MCF-7 cell line has a high expression level of estrogen receptor alpha (ER-α), the corresponding monoclonal antibodies (mAb) of ER-α were covalently functionalized onto the polyacrylic acid (PAA) stabilized NaYF₄:Yb³⁺,Er³⁺ UCNPs synthesized from an organic solvent into hydrophilic ones via a simple EDC cross-linking method (as illustrated in Fig. 1), aiming to achieve a highly sensitive upconversion luminescence (UCL) imaging platform for target labeling of the early stage tumor spheroid transplanted in the chick embryo CAM.

The surface modification process was carried out to transfer the hydrophobic NaYF₄:Yb³⁺,Er³⁺ UCNPs synthesized from an organic solvent into hydrophilic ones via a simple two-step ligand exchange method. As illustrated in Fig. 1, the oleic acid (OA) capped outside UCNPs were removed by protonation treatment to obtain ligand free UCNPs, followed by the treatment with poly acrylic acid on the ligand free nanoparticles, anchoring the UCNPs with carboxylic groups. Fig. 2A and B show the TEM images of ligand free and PAA coated NaYF₄:Yb³⁺,Er³⁺ UCNPs. Both ligand free and PAA coated nanoparticles have good dispersibility and uniform size distribution with an average size of around 45 nm. Fig. 2C shows the high resolution TEM image of an individual nanoparticle, where the lattice fringes with interplanar spacing are about 0.52 nm, corresponding to the (100) plane of hexagonal-phase structured NaYF₄. The inset shows the fast Fourier-transform (FFT) diffractogram, confirming the hexagonal-phase of the UCNPs. To prove that the PAA molecules were capped on NaYF₄:Yb³⁺,Er³⁺ UCNPs, Fourier transform infrared spectroscopy (FTIR) characterization was performed (Fig. 2D).

The band around 1124 cm⁻¹ is due to the C=O stretching vibration of the carboxyl groups, and the two strong bands centered at 1580 cm⁻¹ and 1462 cm⁻¹ are associated with the asymmetric and symmetric stretching vibration modes of the carboxylate anions, suggesting the effective COO-RE³⁺ complexation on the UCNP surface. The band at 1728 cm⁻¹ is assigned to the C=O stretching vibration of the free carboxyl groups on the PAA polymer chain.

It is known that the hydrodynamic diameters and surface charges affect greatly cellular endocytosis and toxicity. Therefore, we have measured the hydrodynamic diameters and zeta-potential and the results are shown in Fig. S1. Compared with the ligand free nanoparticles, an increase in hydrodynamic diameters was observed in PAA coated nanoparticles, which may indicate the dwelling effect of polymer layers coated on the surface of UCNPs. A significant change was also observed in the surface charges, varying from 45.5 mV (ligand free UCNPs) to −37.9 mV (PAA coated UCNPs), confirming the existence of carboxyl groups at the surface of UCNPs. The UCL spectra of the ligand free and PAA coated NaYF₄:Yb³⁺,Er³⁺ UCNPs with the same concentration (1 mg mL⁻¹) in water at 980 nm excitation of 400 mW are given in Fig. S2. The upconversion luminescence in the visible region has two bands, a green one around 515–560 nm and a red one around 640–675 nm, which are ascribed to transitions of 4S3/2→4I15/2 and 4F9/2→4I15/2 from the doped Er³⁺ ions, respectively. The two UCL spectra are similar, indicating that the polymer coating has a negligible effect on the luminescence properties of the UCNPs.

Cytotoxicity was investigated on two different cell lines, human breast adenocarcinoma MCF-7 and mouse embryo fibroblast 3T3, using different concentrations of UCNPs-mAb conjugates (0, 5, 10, 20, 50, and 100 μg mL⁻¹). After 24 h, no significant change was observed in the cell morphology and proliferation of both cell lines in the presence of the UCNPs-mAb conjugates. The cellular viability was evaluated by the MTT assay of the mitochondrial activities and relevant results are shown in Fig. 2E. Both cell lines demonstrate good viability, even at the maximum concentration of 100 μg mL⁻¹, and the viability is greater than 90%. These results indicate that UCNPs-mAb conjugates have good biocompatibility and could be used for in vivo imaging. Fig. 3 shows the confocal microscopy images of MCF-7 breast adenocarcinoma cells (positive) and 3T3 fibroblast cells (negative) after treatment with UCNPs-mAb (100 μg mL⁻¹) for 8 h. The bright field images show that the cellular morphology is intact, which is
consistent with the cytotoxicity results of the UCNPs-mAb conjugates. The dark field images show the upconversion luminescence within the MCF-7 cells, whereas little luminescence was observed in the 3T3 cells. The latter is related to the residual non-specific adsorption of the UCNPs on the 3T3 cell membranes. These results indicate that the UCNPs-mAb conjugates can specifically label on the MCF-7 breast cancer cells.

In our study a shell-less cultured chick embryo was developed as the model to research the \textit{in vivo} labeling properties of UCNPs-mAb. A typical shell-less chick embryo is shown in Fig. S3.† The CAM membrane is settled on the top of embryo and yolk, and the blood vessels of CAM can be seen very clearly with naked eyes. In order to assess the \textit{in vivo} targeting behavior of the UCNPs-mAb conjugates on early stage cancer spheroids, MCTSs were cultured \textit{in vitro} and transplanted onto the CAM. Compared with the cancer cells cultured in 2-D, the MCTS show a condensed structure in 3-D (Fig. S4†), and can mimic more closely the cellular-matrix and cell-cell interactions \textit{in vivo}.42 After 3 days of incubation, the MCTS could be embedded into the CAM membrane (Fig. S5†), and the newly grown blood vessels can be clearly seen surrounding the MCTS. Then UCNPs-mAb were systematically administrated into the chick embryo CAM via venule injection under a stereomicroscope. Owing to the depression of autofluorescence during UCL imaging, the microcirculating behavior of the nanoconjugates in blood vessels was able to be neatly investigated with a modified fluorescence intravital microscope. The UCNP without any antibody functionalization (non-functionalized UCNP) were also injected for control, data are shown in Fig. 4A. We see that the non-functionalized UCNP were present in both the MCTS and the surrounding tissue without specific accumulation within the MCTS, both at 1 h and at 24 h after injection. In contrast, the functionalized UCNP-mAb were accumulated specifically on the MCTS (Fig. 4B). One hour after injection, the UCNPs-mAb were observed mainly in the surrounding tissue of the MCTS. Twenty-four hours after injection, strong upconversion luminescence was obviously observed in the MCTS, indicating the good targeted delivery of UCNPs-mAb conjugates.

In order to further demonstrate the selective labeling of UCNPs-mAb in tumor cells, the resected MCTS region was histologically examined (Fig. 5). Fig. 5A shows the microscopy images of the H&E stained MCTS embedded into the CAM tissue. Fig. 5B and C are the confocal upconversion luminescence images of CAM and MCTS corresponding to the marked areas in Fig. 5A. As expected, normal CAM regions show very low amount or no luminescence of UCNPs-mAb (Fig. 5B), whereas targeted luminescence of UCNPs-mAb was only observed in the transition zone from the CAM into the MCTS (Fig. 5C). Low fluorescence was detected from the surrounding tissue, resulting in a high contrast between targeted MCF-7 cells and the surrounding tissue. In contrast, from the histological examination of MCTS administered with non-functionalized UCNP, only very little amount of upconversion luminescence was observed in the MCTS.
Conclusions

In conclusion, NaYF₄:Yb,Er upconversion nanoparticles have been successfully functionalized and employed for target labeling the cancer at an early stage in the CAM model. PAA coated UCNPs were synthesized by a two-step ligand exchange method, and functionalized with ER-α monoclonal antibodies to obtain UCNPs-mAb conjugates. \textit{In vitro} research studies reveal that the UCNPs-mAb conjugates have no significant cytotoxicity on mammalian cells, and can specifically label in the MCF-7 breast cancer cells rather than in the normal cells. The cellular viability was higher than 90% even at a relatively high concentration (100 \ mg L⁻¹) of UCNPs-mAb. The 3-dimensional MCTS (∼500 μm) transplanted CAM model has been developed as the early stage tumor model to research the \textit{in vivo} labeling properties of UCNPs-mAb. Intravital microscopy imaging demonstrated that intravenously injected UCNPs-mAb conjugates have high specificity in labeling the breast cancer. Our work suggests that UCNPs-mAb, in combination with CAM, offer a new possibility in early cancer studies.
