(Received 11 June 2014; published 4 March 2015)

An essential part of high-energy hadronic collisions is the soft hadronic activity that underlies the primary hard interaction. It includes soft radiation from the primary hard partons, secondary multiple parton interactions (MPI), and factorization-violating effects. The invariant mass spectrum of the leading jet in $Z +$ jet and $H +$ jet events is directly sensitive to these effects, and we use a QCD factorization theorem to predict its dependence on the jet radius $R$, jet $p_T$, jet rapidity, and partonic process for both the perturbative and nonperturbative components of primary soft radiation. We prove that the nonperturbative contributions involve only odd powers of $R$, and the linear $R$ term is universal for quark and gluon jets. The hadronization model in PYTHIA8 agrees well with these properties. The perturbative soft initial state radiation (ISR) has a contribution that depends on the jet area in the same way as the underlying event, but this degeneracy is broken by dependence on the jet $p_T$. The size of this soft ISR contribution is proportional to the color state of the initial partons, yielding the same positive contribution for $gg \rightarrow Hg$ and $gg \rightarrow Zg$, but a negative interference contribution for $q \bar{q} \rightarrow Zg$. Hence, measuring these dependencies allows one to separate hadronization, soft ISR, and MPI contributions in the data.

Soft hadronic activity plays a role in practically all but the most inclusive measurements at the LHC. It is often an important yet hard-to-quantify source of uncertainty, so improving its theoretical understanding is vital. One can consider four conceptually different sources for the effects that are experimentally associated with soft hadronic activity and the underlying event (UE): 1. perturbative soft radiation from the primary incoming and outgoing hard partons within factorization, 2. nonperturbative soft effects within factorization associated with hadronization, 3. multiple parton interactions (MPI) at lower scales in the same proton-proton collision, and 4. factorization breaking contributions. For any given observable, the question is how much of each of these sources is required to describe the data. For example, it is known that including higher-order perturbative corrections (source 1) in parton-shower Monte Carlo programs can give a nontrivial contribution to traditional UE measurements [1,2].

Traditionally, the UE activity is measured in regions of phase space away from hard jets [2–12]. These results are used to tune the MPI models which describe the UE in Monte Carlo programs [13–18]. These models are then extrapolated into the jet region, where they are used to describe various jet observables, including the jet mass spectrum in dijet and Drell-Yan events [19,20], which is an important benchmark jet observable at the LHC.

In this Letter, we directly consider the jet region and give a field-theoretic description of primary soft effects (sources 1 and 2), and discuss how to distinguish sources 1, 2, and 3.

This is done using the dependence of the jet mass spectrum and its first moment on the jet radius $R$, jet momentum $p_T$, jet rapidity $y_J$, and participating partons. We will not consider factorization-breaking effects here (see, e.g., Ref. [21]).

We consider the jet mass spectrum in exclusive $pp \rightarrow Z + 1$ jet and $pp \rightarrow H + 1$ jet events. The factorization formula for $m_J \ll p_T^J$ that includes sources 1 and 2 is given by [22–24]

$$
\frac{d\sigma}{dm_J^2 d\Phi_2} = \sum_{\kappa,a,b} H_\kappa(\Phi_2) \int dk_S dk_B (\mathcal{I}_{\kappa,a} \mathcal{I}_{\kappa,b} \otimes f_a f_b)(k_B) \\
	imes J_{\kappa}(m_J^2 - 2p_T^J k_S) S_\kappa(k_S, p_{cut} - k_B, y_J, R).
$$

(1)

Here, $\Phi_2 = \{p_T^J, y_J, Y\}$, $Y$ is the rapidity of the $Z/H +$ jet system, $\kappa$ denotes the partonic channel, and $k_S$ and $k_B$ account for soft contributions to the jet mass $m_J^2$ and jet veto $p_{cut}$ (which vetoes additional jets). The $H_\kappa(\Phi_2)$ contains the perturbative matrix elements for the hard process, and $\mathcal{I}_{\kappa,a} \mathcal{I}_{\kappa,b} \otimes f_a f_b$ describes perturbative collinear initial-state radiation convolved with the parton distribution functions. For the normalized jet mass spectrum, the dependence on $p_{cut}$ largely drops out [24]. As a result, the shape of the jet mass spectrum is determined by the jet function $J_{\kappa}$, describing energetic final-state radiation, and by the soft function $S_\kappa$. See also Refs. [25,26].

The soft function $S_\kappa$ describes the primary initial and final-state soft radiation. It depends on the jet through $y_J$ and $R$ but not $p_T^J$, and can be factorized as [27–29].
In this region, factorization predicts a shift in the tail, and a simple convolution everywhere, for both quark jets (left panel) and gluon jets (right panel).

In the perturbative tail of the jet mass spectrum, where \( k_S \gg \Lambda_{\text{QCD}} \), \( S_k \) can be expanded,

\[
S_k(k_S, y_J, R) = \int dk S_k^\text{pert}(k_S-k, k_B, y_J, R) \times F_s(k, y_J, R)[1 + O(\Lambda_{\text{QCD}}/k_B)],
\]

where \( S_k^\text{pert} \) contains the perturbative soft contributions. \( F_s \) is a normalized nonperturbative shape function which encodes the smearing effect that the hadronization has on the soft momentum \( k_S \). For \( k_S \sim \Lambda_{\text{QCD}} \), the full \( F_s(k) \) is required and shifts the peak region of the jet mass spectrum to higher jet masses.

In the perturbative tail of the jet mass spectrum, where \( k_S \gg \Lambda_{\text{QCD}} \), \( S_k \) can be expanded,

\[
S_k(k_S, y_J, R) = S_k^\text{pert}(k_S - \Omega_s(R), y_J, R) + O(\Lambda_{\text{QCD}}^2/k_3^2, \alpha_s \Lambda_{\text{QCD}}^2/k_3^2),
\]

where \( \Omega_s(R) = \int dk k F_s(k) \sim \Lambda_{\text{QCD}} \) is a nonperturbative parameter. In this region, factorization predicts a shift in the jet mass spectrum, which is described by \( \Omega_s(R) \). Below, we use the field-theoretic definition of \( \Omega_s \) to quantify its \( R \) dependence and prove that it is independent of \( y_J \). The above treatment provides an excellent description of hadronization in both \( B \)-meson decays and \( e^+e^- \) event shapes [30,31].

Factorization also underlies the Monte Carlo description of the primary collision, where \( H \) corresponds to the hard matrix element, while \( T, J, \) and \( S \) are described by parton showers, and \( F \) corresponds to the hadronization models. The standard parton shower paradigm does not completely capture interference effects between wide-angle soft emissions from different primary partons that appear at \( O(\alpha_s) \) in \( S_k \). Monte Carlo programs include MPI (source 3), which are not in Eq. (1). See Ref. [32] for a recent discussion. For our numerical studies, we consider both PYTHIA8 [33,34] with the ATLAS underlying event tune AU2-MSTW2008LO [16] and HERWIG++ 2.7 [35,36] with its default underlying event tune UE-EE-5-MRST [18]. Both give a reasonable description of the CMS jet mass spectrum in \( Z \) + jet events [20]. We also compare to the PYTHIA8 default tune 4C.

We consider exclusive \( Z/H + \) jet events at \( E_{cm} = 7 \) TeV in both quark and gluon channels, with the leading jet within a certain range of \( p_T^J \) and \( y_J \), and we veto additional jets with \( p_T^J > 50 \) GeV. The jets are defined using anti-\( k_T \) [37,38]. In Fig. 1, we show the jet mass spectrum for quark and gluon jets with \( R = 1 \) after parton showering (black dotted line) and including both hadronization and MPI (blue dashed line). Equation (3) predicts that for \( m_J^2 \gg \Lambda_{\text{QCD}}^2 p_T^J \) the nonperturbative corrections shift the tail of the jet mass spectrum by

\[
m_J^2 = (m_J^2)^\text{pert} + 2 p_T^J \Omega_s(R).
\]

We can regard the partonic result from PYTHIA8 as the baseline purely perturbative result. Choosing \( \Omega = 2.4 \) GeV for \( qg \to Zq \) and \( \Omega = 2.7 \) GeV for \( q\bar{q} \to Zg \) yields the green dot-dashed curves in Fig. 1. We see that the effect of both hadronization and MPI in the tail is well captured by this shift. For hadronization, Eqs. (1), (2) predict a convolution with a nonperturbative function,

\[
\frac{d\sigma}{dm_J^2} = \int dk \frac{d\sigma^{\text{partonic}}}{dm_J^2} (m_J^2 - 2 p_T^J k) F_s(k).
\]
We consider the first moment in $m_T^2$,

$$M_1 = \frac{1}{\sigma} \int dm_T^2 \frac{m_T^2}{dm_T^2}, \tag{6}$$

which tracks the shift observed in Fig. 1. Taking the first moment of Eq. (1) combined with Eqs. (2) and (3), we can compute the dependence of primary soft radiation on $p_T$, $y$, $R$, and partonic channel, giving

$$M_1 = M_{1k}^{pert}(p_T, y, R) + 2p_T \Omega_k(R). \tag{7}$$

Here, $M_{1k}^{pert}(p_T, y, R)$ contains all perturbative contributions, while $\Omega_k(R)$ encodes the shift due to nonperturbative effects.

For $pp \rightarrow H/Z + \text{jet}, \, \Omega_k(R)$ is given by the vacuum matrix element of lightlike soft Wilson lines $Y_a, \, Y_b$, and $Y \equiv Y(y, \phi, R)$ along the beam and jet directions,

$$\Omega_k(R) = \int_0^1 dr \int_\infty^\infty dy \int_0^{2\pi} d\phi f(r, y - y_j, \phi - \phi_j, R) \times \langle 0|T[Y^a_j Y^b_j]T[Y, Y_j]|0\rangle. \tag{8}$$

Here, the rapidity $y$, azimuthal angle $\phi$, and transverse velocity $r = p_T/m_T$ are measured with respect to the beam axis. The color representation of the Wilson lines depends on the partonic channel, giving the $\kappa$ dependence of $\Omega_k$. The jet mass measurement function is $f(r, y, \phi, R) = \langle \text{cosh} \, y - r \cos \phi |b(y, \phi, r) < R^2\rangle$, where $b(y, \phi, r)$ specifies the jet boundary. The matrix element involves the energy flow operator $[39-43] \tilde{E}_T(r, y, \phi)|X\rangle = \sum_{i \in X} m_T \delta(r - r_i) \delta(y - y_i) \delta(\phi - \phi_i)|X\rangle$. From Eq. (8), it follows immediately that $\Omega_k(R)$ is independent of $p_T^2$.

Using invariance under boosts and rotations, we can prove that it is also independent of $y_j$ and $\phi_j$ (see the Supplemental Material [44]).

Expanding Eq. (8) for small $R$, we find [44,45]

$$\Omega_k(R) = \frac{R}{2} \Omega_k^{(1)} + \frac{R^3}{18} \Omega_k^{(3)} + \frac{R^5}{32} \Omega_k^{(5)} + O\left(\left(\frac{R}{2}\right)^7\right), \tag{9}$$

where the $\Omega_k^{(i)}$ are $R$ independent and only odd powers of $R$ occur. This $R$ scaling of our nonperturbative operator for jet mass agrees with that found in Ref. [46] from a QCD hadronization model. Our operator definition implies a universality for the linear $R$ nonperturbative parameter in Eq. (9). For $R \rightarrow 0$, the beam Wilson lines fuse into a Wilson line in the conjugate representation to the jet, $Y_\lambda Y_{\bar{\lambda}} \rightarrow Y_\lambda$. The result is given by (see the Supplemental Material [44])

$$\Omega_k^{(1)} = \int_0^1 dr/\langle 0|T[Y^a_j Y^b_j]T[Y, Y_j]|0\rangle, \tag{10}$$

which only depends on whether the jet is a quark or gluon jet. For quarks, we can compare this to thrust in deep-inelastic scattering (DIS) [47], where precisely this parameter $\Omega_k^{(1)}$ appears [48].

Consider next $M_{1k}^{pert}$ in Eq. (7). Dimensional analysis and the kinematical bound $m_T \lesssim p_T^2 R^2$ imply that $M_{1k}^{pert}$ scales like $(p_T^2 R^2)^2$. Resummation modifies the leading $R$ dependence to $R^{2-\gamma_\kappa}$, where $\gamma_\kappa \sim \alpha_s > 0$. The soft function contains a contribution due to interference between ISR from the two beams (see the Supplemental Material [44]).

$$S_k^{pert}(k) \sim \frac{\alpha_s C_F}{\pi} R^2 \left(\frac{\mu}{k}\right)^{2-\gamma_\kappa}. \tag{11}$$

The extra $R^2$ for soft ISR causes it to contribute to $M_{1k}^{pert}$ as $(p_T^2 R^2)^4$ with the color factors

$$C_{qq\rightarrow q} = C_{gg\rightarrow g} = \frac{C_A}{2} = \frac{3}{2}, \quad C_{qg\rightarrow g} = C_F - \frac{C_A}{2} = \frac{1}{2}. \tag{12}$$

The above factorization results can be compared to PYTHIA8 and HERWIG++, where we find that the dependence of $M_1$ on $p_T^2, \, y_j, \, \kappa$, is well described by

FIG. 2 (color online). The $R$ dependence of $\Omega_{\text{had}}^{(1)}(R)$ extracted from $M_1$ in PYTHIA8 (left panel) and HERWIG++ (right panel), shown as dots, triangles, and squares for different channels. The fit using Eq. (9) (shown by lines) demonstrates the agreement with factorization. The small-$R$ behavior only depends on whether the jet is initiated by a quark (blue dashed line) or gluon (orange solid and green dotted lines).
\[ M_1 = M_{1x}^{\text{partonic}}(p_T, y_J, R) + 2p_T^2 \Omega_{x}^{\text{had}}(R) + 2p_T^2 [\Upsilon^{\text{MPI}}(y_J, R) + \Omega_{x}^{\text{MPI}}(y_J, R)]. \]  

Here, \( M_{1x}^{\text{partonic}} \) is the partonic contribution, \( \Omega_{x}^{\text{had}} \) is defined by partonic → hadronic, and \( \Upsilon^{\text{MPI}} \) by partonic → partonic + MPI. The small remainder from hadronization of the MPI, \( \Omega_{x}^{\text{MPI}} \), is defined to ensure the sum of terms yields the full partonic → hadronic + MPI. Note that hadronization and MPI contributions are each individually described by shifts to \( M_1 \). Also, the independence of \( \Omega_x \) to \( y_J \) and \( p_T \) is observed in both PYTHIA8 and HERWIG++ (see the Supplemental Material [44]). Equation (13) contains MPI contributions with no analog in Eq. (7).

The hadronization \( \Omega_{x}^{\text{had}}(R)/(R/2) \) from PYTHIA8 and HERWIG++ is shown in Fig. 2 for different channels. For \( R \ll 1 \), \( \Omega_{x}^{\text{had}}(R) \) is linear in \( R \) and has the same slope for the two channels involving gluon jets, as predicted by factorization. For PYTHIA8, all channels differ for large \( R \) and can be fit to the factorization form in Eq. (9). For the quark jet, we extract \( \Omega_{q}^{(1)} = 1.2 \text{ GeV} \) and for gluon jets \( \Omega_{g}^{(1)} = 2.2 \text{ GeV} \). For \( qg \rightarrow Zq \) and \( qg \rightarrow Hg \) the \( R \) dependence is strong enough that an additional \( R^2 \) contribution is disfavored in the fit. For HERWIG++, the dependence on higher powers of \( R \) is much weaker, and \( \Omega_{q}^{(1)} \approx \Omega_{g}^{(1)} \). The full set of fit coefficients is in the Supplemental Material [44].

In Fig. 3, we compare our perturbative next-to-leading logarithmic (NLL) and next-to-next-to-leading logarithmic (NNLL) factorization predictions [24] for \( M_{1x}^{\text{partonic}} \) to the corresponding \( M_{1x}^{\text{partonic}} \) from PYTHIA8 and HERWIG++ as a function of \( R \), dividing by the leading \( R^2 \) dependence. The \( R^4 \) contribution from soft ISR only enters at NNLL and is seen in the rise at large \( R \) for \( qg \rightarrow Zq \) (left panel). This effect is partially modeled by soft emissions in the parton shower, which explains the similar \( R^4 \) contribution for \( qg \rightarrow Zq \) in PYTHIA8 and HERWIG++. For \( q\bar{q} \rightarrow Zg \) (right panel), Eqs. (11) and (12) predict the \( R^4 \) contribution from soft ISR to be negative, which we observe at NNLL. This negative interference effect is not captured by these Monte Carlo programs.

The apparent ambiguity between \( R^4 \) contributions from soft ISR and MPI can be resolved through their \( p_T^4 \) dependence. In Fig. 4, we show the \( R^4 \) component \( c_4^T \) of the partonic moment, obtained by fitting

\[ \frac{M_{1x}^{\text{partonic}}}{2p_T^4 R^2} = c_4^T R^{-\gamma_4} + c_4^R R^2, \]

and also the MPI contribution to the moment, \( \Upsilon^{\text{MPI}}/R^2 \sim R^2 \). The differences between various tunes for \( c_4^T \) and \( \Upsilon^{\text{MPI}} \) reflects their apparent ambiguity, whereas their sum agrees much better. The \( p_T^4 \) dependence clearly resolves the ambiguity: \( c_4^T \sim p_T^4 \) as predicted by factorization, whereas \( \Upsilon^{\text{MPI}} \) is independent of \( p_T^4 \). As shown in the Supplemental Material [44], the channel dependence could

FIG. 3 (color online). \( R \) dependence of the perturbative jet mass moment \( M_{1x}^{\text{partonic}} \) at NLL and NNLL accuracy and the partonic jet mass moment \( M_{1x}^{\text{partonic}} \) in PYTHIA8 (tune AU2 and 4C) and HERWIG++ for \( qg \rightarrow Zq \) (left panel) and \( q\bar{q} \rightarrow Zg \) (right panel). The soft ISR contribution \( \sim R^4 \) is well modeled by Monte Carlo programs for \( qg \rightarrow Zq \), but not for the destructive interference in \( q\bar{q} \rightarrow Zg \).
also be used to separate soft ISR from MPI: $c_4^\gamma$ depends on the color channel as in Eq. (12), whereas $c_4^{\gamma_{\text{MPI}}}$ is channel independent. Also, the $\gamma_j$ dependence of soft ISR is quite different between HERWIG++ and PYTHIA8.

To conclude, we have used QCD factorization to predict the properties of the perturbative and nonperturbative components of primary soft radiation for jet mass in $pp \rightarrow H/Z + \gamma$. We have shown that the nonperturbative soft effects involve odd powers of $R$ and are universal for quark and gluon jets for $R \ll 1$. Hadronization models in Monte Carlo programs agree with these predictions. The perturbative soft radiation has a contribution that scales like $R^4$, just like the contribution from MPI. These components depend differently on $p_T^J$ and on the partonic process. Hence, separately measuring quark and gluon channels in Drell-Yan events and in different bins of $p_T^J$ provides the possibility to clearly distinguish between MPI and primary soft radiation.
