Law and Culture: A Theory of Comparative Variation in Bona Fide Purchase Rules

Giuseppe Dari-Mattiacci* and Carmine Guerriero†‡

Abstract—A key question in comparative law is why different legal systems provide different legal solutions for the same problem. To answer this question, we use novel comparative evidence on how the conflict between the dispossessed original owner and the bona fide purchaser of a stolen good is resolved in different countries. This is the most primitive manifestation of a fundamental legal choice: the balance between the protection of the owner's property rights and the enhancement of the buyer's reliance on contracts. We test four prominent theories: functional equivalence, legal origins, political economics and cultural economics. We find that a culture of self-reliance is the key determinant of comparative variation in this area of law.

Keywords: culture, comparative variation, legal origins, functional equivalence, good faith purchase

1. Introduction

Why do different legal systems adopt different legal rules dealing with the same problem? This is a fundamental question in comparative law. Yet there...
is no consensus as to whether these differences are substantial or merely superficial, nor about their causes. Among the theories that have been proposed, it is possible to identify four main clusters: functional equivalence, legal origins, political economics and cultural economics. The first approach stresses the functional equivalence among different legal rules and ascribes residual divergence to the idiosyncratic preferences of the lawmaker. In contrast, the other approaches view the differences among legal systems as substantial and attribute them to a transplantation process mainly due to colonisation, to different features of the political system, or to different cultural backgrounds.

The present article informs this debate by empirically testing these four theories on a specific legal issue: the conflict between the dispossessed owner and the bona fide purchaser for value of stolen personal property, that is, movable goods in private law parlance. While our empirical findings only apply to this specific context, the conflict between dispossessed owners and bona fide purchasers is the most primitive manifestation of a much more general and fundamental legal problem that every legal system, from the code of Hammurabi, the Talmud and ancient Greek and Roman law to modern civil and common law systems, has felt the need to address explicitly: the balance between protecting property rights and enhancing reliance on contracts, which we call the ‘property–contract balance’.

Before asking why there is comparative variation, we need to show that there is comparative variation. This issue is surprisingly unsettled. Using a novel and comprehensive cross-country dataset, we document and measure the extent to which legal systems diverge in the protection of the original owner versus the bona fide purchaser. Adding to the growing literature on quantitative comparative law, our measurement exercise is based on several indicators gauging the number of years after which the buyer is immune from the owner’s claims under a variety of circumstances. In the case of private sales, while in the United States the original owner of stolen personal property can virtually always reclaim it from the bona fide purchaser under the ‘theft rule’, he or she can only do so within 30 years in South Africa. This term is reduced to ten years in Germany, eight years in Russia, six years in England and

7 Uniform Commercial Code, ss 1–103.

9 German Civil Code, ss 935 and 937.

Wales,\textsuperscript{11} five years in Turkey,\textsuperscript{12} and three years in France,\textsuperscript{13} while in Italy the purchaser is immediately protected.\textsuperscript{14} Figure 1 provides a visual representation of the distribution of these terms of years (the variable named \textit{Property–Private}) around the world.

Because of this large amount of comparative variation, rules concerning the bona fide purchase of stolen goods are naturally suited to address empirically our primary question: why is there comparative variation? Following the lead of Amir Licht, Chanan Goldschmidt and Shalom Schwartz and building on a long legacy of cross-cultural psychology and economics,\textsuperscript{15} we document a relationship between law and prevalent cultural values. In particular, we find that jurisdictions in which individuals display a stronger culture of morality, embodied by stronger norms of trust and respect for others, as self-reported to the World Value Study and the European Value Survey up to the 2008 (the variable named \textit{Culture}),\textsuperscript{16} exhibit stronger owner protection. In addition, jurisdictions in which there is stronger enforcement of the law, as measured by the number of police personnel and professional judges per 100,000 inhabitants over the 1973–2009 period (the variable named \textit{Enforcement}),\textsuperscript{17} exhibit weaker owner protection. While the left graph of Figure 2 depicts the positive relationship linking \textit{Property–Private} and \textit{Culture}, once the role of \textit{Enforcement} is

Figure 1. Owner Protection in Private Sales Around the World (sample size: 126)
Figure 2. Effects of Culture and Enforcement on Owner Protection in Private Sales (sample size: 77)
considered, the right graph of Figure 2 displays the negative link existing between Property–Private and Enforcement once Culture is taken into account.

An explanation for these patterns is that in developed markets buyers tend to value goods more than their original owners and, thus, society faces a trade-off between the basic need of safeguarding the original owners’ property and leaving some stolen goods in the hands of those who value them the most, that is, the buyers. Since a culture of morality assures that most transactions are legal, condoning some non-consensual transfers is less useful. Similarly, stronger law enforcement raises the number of goods that are returned to low-valuing owners and hence needs to be counterbalanced by weaker owner protection. In a companion paper written with Zhenxing Huang, we develop a formal version of this value-based theory and explore its relation with the incentive theory. 18

Although these correlations are suggestive, they could be due to reverse causation, that is, it could be the law that affects a culture of morality and the strength of enforcement rather than the other way around. 19 Therefore, we need to focus on fundamental, yet measurable features of a country’s culture that affect the law but are unlikely to be affected by it. Basic features of languages, such as pronoun usages, have been shown to embed fundamental characteristics of the speaker’s culture and hence can be substituted to our two cultural dimensions in our empirical analysis. Amnon Lehavi and Amir Licht were the first to use this approach to study property law. 20 The two features of language that we will use in the analysis are ‘pronoun drop’ and ‘pronoun difference’. Pronoun drop refers to the possibility of dropping the first person pronoun, which is not allowed in English, where ‘I’ must accompany the verb. Pronoun difference refers to the use of formal and informal second person pronouns, such as ‘ye’ and ‘thou’ in early English or ‘tu’ and ‘vous’ in French. These language features are statistically related to the cultural variables in which we are interested: pronoun drop is typical of societies that emphasise individual freedom less and in which, therefore, trust and respect for others are more limited, whereas pronoun difference is typical of societies accommodating hierarchical control and, in turn, stronger law enforcement. 21

18 See G Dari-Mattiacci, C Guerriero and Z Huang, ‘The Property–Contract Balance’ (manuscript on file with the authors, 2014).
20 A Lehavi and A Licht, ‘BITs and Pieces of Property’ (2011) 36 Yale J Int'l L 115. Their study concerns the protection of property as such and not the property–contract balance. Our results on adverse possession (reported in the Appendix) confirm their results.
21 We combine two well-known approaches: GH Hofstede, Culture’s Consequences: International Differences in Work-Related Values (Sage 1980) (classifying culture along the individualism–collectivism dimension); SH Schwartz, ‘Beyond Individualism/Collectivism: New Cultural Dimensions of Values’ in K Uichol and others (ed), Individualism and Collectivism: Theory, Method, and Applications (Sage 1994) (classifying culture along the hierarchy–egalitarianism dimension). See also JI Siegel, AN Licht and SH Schwartz, ‘Egalitarianism and International Investment’ (2011) 102 J Fin Econ 621. We formally test the first stage relationship linking on the one hand culture to pronoun drop and on the other hand enforcement and pronoun difference in the Appendix.
Therefore, instead of employing culture directly, we can rely on its exogenous determinants and so avoid reverse causality. To make the analysis easier to follow, it is useful to condense the two grammatical features in a single dimension that we call **self-reliance**. This is high if a language has no pronoun drop (high trust and respect) and no pronoun difference (weak enforcement) and low in the opposite case. Intermediate levels of self-reliance correspond to cases in which only one of the two language features is present. Figure 3 provides a snapshot of self-reliance around the world as measured by pronoun use.

Essentially, our empirical investigation aims at statistically establishing a relationship between the data depicted in Figure 1 and the data depicted in Figure 3. Section 2 provides the building blocks of our empirical analysis. In 2A, we offer a detailed description both of the method of collecting the data and of their features. In 2B, we illustrate the theoretical background of the analysis and offer a rationale for the relationship between bona fide purchase rules and culture. In 2C we formulate our hypothesis. In 2D, we document the relationship between language and culture and substantiate our choice of language as a proxy for culture. In 2E, we offer a historical argument to support our claim that differences in culture cause differences in law.

Section 3 contains our comparative exercise. In 3A to 3C, we compare the explanatory power of culture with that of the functional equivalence theory, the legal origins theory and two political economy theories, respectively. In 3D, we introduce a competing cultural trait based on religion and contrast it with our self-reliance explanation. Our empirical results document that countries with a higher degree of self-reliance tend to exhibit a higher degree of owner protection. For example, the United States has a higher degree of both self-reliance and owner protection than Italy. Furthermore, self-reliance consistently provides a better explanation than competing theories. In section 4, we conclude with a brief description of an interdisciplinary research agenda on comparative variation and legal harmonisation. The data, the codes and additional robustness results are available in an online Appendix.

2. **Innocent Purchase of Stolen Goods**

A. **The Data**

The conflict arising between the original owner and the bona fide purchaser of a stolen movable good is an ideal case to study because it is at the heart of

22 See Appendix.

23 The Appendix is available on the journal website as well as at <https://sites.google.com/site/carmineguerrieroshomepage/home/research-1> accessed 18 January 2015.
Figure 3. Self-reliance Around the World (sample size: 107)
private law in any legal system that recognises private property. The problem can be easily defined in factual terms, given that the notions of 'stolen movable good' and 'purchase for value' are rather uniformly understood. There is a natural measure for the degree of protection that a legal system affords to owners versus buyers: the number of years after which an innocent purchaser acquires ownership of a stolen good. The longer this period, the more protected the original owner. We focus on cases in which the good is stolen and immediately resold, so as to avoid the problem of determining whether this term of years starts running from the moment of theft or from the purchase.

This information has been collected with the help of 148 teams of experts in 126 jurisdictions, whose names are listed in the Appendix. These experts are renowned professors of private (mostly property) law in one of the leading universities of their respective jurisdictions, or practitioners in prominent international law firms. A large fraction of them have already participated in comparative projects. The experts were asked to provide a detailed answer to the following main question and a number of follow-up questions: ‘At what conditions does a good faith buyer acquire ownership of a stolen good?’ From their answers, we distilled the relevant conditions and constructed indexes of owner protection concerning the bona fide purchase for value without notice of stolen personal property through a private sale, in a public market, from a professional seller, and in an auction. In each case, we also recorded information as to whether the party who has the right to retain the good is required to pay compensation to the other party. While none of the countries in our sample conditions a buyer’s ownership claim to the payment of compensation to the original owner, many countries have the opposite rule, requiring the owner to compensate the buyer if he or she reclaims the good.

25 We refer to jurisdictions since we differentiate among England and Wales, Northern Ireland and Scotland. The data also contains Canada, which was excluded from the statistical analysis because we only have information on Quebec.

26 The questionnaire was drafted by Giuseppe Dari-Mattiacci, Carmine Guerriero and Arthur Salomons, while the data was collected by Giuseppe Dari-Mattiacci and Carmine Guerriero.

27 In doing so we aimed at accounting not only for the legal rules in force but also for the way in which such rules are applied in practice as a result of the complex interaction of the different legal formants. See Sacco, ‘Legal Formants’ (n 1) 21, 27–30; PG Monateri, ‘Methods in Comparative Law: An Intellectual Overview’ in PG Monateri (ed), Methods of Comparative Law (Elgar 2012) 7; BC Canon and L Baum, ‘Patterns of Adoption of Tort Law Innovations: An Application of Diffusion Theory to Judicial Doctrines’ (1981) 75 Am Pol Sci Rev 975.

28 This rule amounts to an option for the owner to buy back his good and has a long history: it was included in the Code of Hammurabi, in Germanic law, in Burgundian and Visigothic law, while Hebraic laws gave the owner an option to buy back as long as he had not abandoned hope of locating his property, see Murray (n 5) 29, 82–88; B Kozolchyk, ‘Transfer of Personal Property by a Nonowner: Its Future in Light of Its Past’ (1987) 61 Tul L Rev 1453, 1484–85. Consequently, the buyer might be protected with a property rule (if the buyer can retain the good) or a liability rule (if the buyer receives compensation instead of the entitlement). The owner is always protected with a property rule instead (if protected at all): G Calabresi and AD Melamed, ‘Property Rules, Liability Rules, and Inalienability: One View of the Cathedral’ (1972) 85 Harv L Rev 1089.
The amount of compensation is equal either to the purchase price or to the market price of the good. In addition, we collected information about the definition of good faith—subjective (‘did not know’) or objective (‘did not know and ought not to have known’)—and about whether good faith is presumed or must be proven by the buyer.

Finally, we also recorded background rules of adverse possession (also including acquisitive prescription) for personal property and statutes of limitation for the remedies available to the owner. These rules resolve the more general conflict between the original owner and a possessor of personal property. They are not always directly applicable to the innocent purchase of stolen goods, since adverse possession is often excluded for stolen goods. Moreover, statutes of limitations often run from the moment at which the owner has or could have reasonably located the good. Yet, in other cases, these rules are directly relevant because the general adverse possession term applies also to stolen goods or because the statute of limitations starts running from the moment of theft. In such cases, we have taken these rules into account while constructing our other indexes of owner protection.

Table 1 provides a snapshot of the indexes for owner protection for the four countries that we use as examples. As anticipated, a larger term of years indicates stronger owner protection (and hence weaker buyer protection). ‘Never’ implies pure owner protection, while a value equal to zero implies the complete protection of the bona fide purchaser who acquires ownership immediately at the moment of the purchase. Figure 4 offers an overview of our data. The first three indexes refer to general property law rules, while the last four indexes are specific to the case of the innocent purchase of stolen goods. For each index, we report the shares of jurisdictions with pure owner protection (the buyer never acquires ownership or the remedy for the owner never expires), pure buyer protection (the buyer acquires ownership immediately), and intermediate protection (the buyer acquires ownership after a term of years), as measured on the left-hand axis. We also report the mean term of years for the jurisdictions belonging to the intermediate group, as measured on the right-hand axis. The figure shows substantial comparative variation in each of the indexes. The largest group of countries affords original owners intermediate protection. Adverse possession is more frequently available and requires fewer years if the possessor is in good faith. Finally, good faith

---

29 It is necessary for the empirical analysis to assign a finite number of years to the case ‘never’. In the following sections, we report the results for the analysis with ‘never’ equal to thirty years (the highest term of years for the jurisdictions in the intermediate group). The message of our empirical exercise is not very different when we substitute either 70 years or the life expectancy at birth in the jurisdiction for ‘never’.

30 The standard deviation within the intermediate protection countries is 7.4 (adverse possession in good faith), 9.2 (adverse possession in bad faith), 8.6 (prescription of the owner’s remedy), 6.5 (owner protection in private sales), 5.8 (owner protection in markets), 5.8 (owner protection with professional seller) and 4.0 (owner protection in auctions).
buyers of stolen goods are protected more often and more strongly if they purchase in a market, from a professional seller or in an auction than if they purchase through a private sale (a generalisation of the market overt rule).

Focusing on cases in which the owner can reclaim the good from a bona fide purchaser (even if there is a term of years; thus, excluding only cases in which there is complete protection of the good faith buyer), the data shows that a majority of the jurisdictions (82% of 110 jurisdictions in case of private sales and 61% of 103 jurisdictions in case of markets, professional sellers or auctions) do not require compensation. Among those requiring compensation,
the measure is in most cases the purchase price (14% in case of private sales and 31% in case of markets, professional sellers or auctions) rather than the market price (5% in case of private sales and 8% in case of markets, professional sellers or auctions). Note that compensation is less frequently required for private sales (19%) than in case of transactions occurring in markets, professional sellers or auctions (40%).

The data also provides information on the definition of good faith and whether it is presumed, limitedly to those jurisdictions where the notion of good faith has a clear definition in the law or in judicial practice (120 jurisdictions). These jurisdictions are almost equally split between objective (46%) and subjective (54%) good faith, whereas in most cases (77%) good faith is presumed.

B. Competing Theoretical Approaches: Incentives Versus Value

The purchase of stolen goods is particularly interesting because the thief is commonly insolvent or not easy to find and hence a court typically needs to adjudicate the case between two equally innocent parties: the dispossessed original owner and the innocent buyer. Although our aim is primarily empirical, it is instructive to illustrate the theoretical background of our exercise. The literature has proposed two approaches to explain the allocation of the good ex post. One approach views the ex post allocation of the contested good as a way to provide incentives to owners and buyers. In a

32 Some authors have argued that buyer protection is necessary for trade: W Blackstone, Commentaries on the Laws of England, vol 2 (Clarendon 1769) 448; Sauveplanne (n 4) 652; R Yaron, ‘Reflections on Usucapio’ (1967) 35 Tijdschrift voor Rechtsgezindheid 191, 223; Kozolchyk (n 28) 1481. Another strand of the literature stresses the importance of owner protection to discourage theft: HR Weinberg, ‘Sales Law, Economics, and the Negotiability of Goods’ (1980) 9 JLS 569; KT Burke, ‘International Transfers of Stolen Cultural Property: Should Thieves Continue to Benefit from Domestic Laws Favoring Bona Fide Purchasers’ (1990) 13 Loy LA Int’l & Comp LJ 427; SF Grover, ‘The Need for Civil-Law Nations to Adopt Discovery Rules in Art Replevin Actions: A Comparative Study’ (1992) 70 Tex L Rev 1431; SA Bibas, ‘The Case Against Statutes of Limitations for Stolen Art’ (1994) 9 JLS 569; cf Merryman, ‘The Good Faith’ (n 5) 281. Other criteria have also been proposed: Levmore, ‘Variety and Uniformity’ (n 3) 47 (considering risk allocation); Landes and Posner (n 5) 188, 206–09 (considering the incentives for the buyer to conceal stolen goods); A Schwartz and RE Scott, Commercial Transactions, Principles and Policies (Found 1982) 510–12 (considering corrective justice along with discouraging of theft); Merrill and Smith (n 4) 840 (arguing that buyer protection means protecting the party with less information and inducing the party with more information to provide notice); A Bell and G Parchomovsky, ‘A Theory of Property’ (2005) 90 Cornell L Rev 531 (arguing that protecting the owner serves to protect the stability of ownership).

nutshell: owners should protect their property, while buyers should inquire about the title of the goods they buy. Legal protection is said to affect these incentives in a predictable way. If the law protects the buyer, owners will have incentives to protect their property while buyers will have no incentives to inquire about the property title. Conversely, if the law protects the original owner, buyers will have incentives to inquire about the title, while owners will have no incentives to protect their property. This approach captures an important aspect of the problem: actions taken by owners and buyers can help reduce the incidence of theft by making either theft more difficult (private protection) or the resale of stolen property less likely (by inquiring about the title), suggesting that the optimal level of legal protection should be set in order to provide the optimal mix of incentives. One important characteristic of the incentive approach is that it calls for a uniform treatment of the good faith purchase problem and does not provide elements for explaining comparative variation. Therefore, it cannot be used to inform an empirical analysis into the causes of comparative variation.

The alternative approach holds that ownership of a stolen good should be assigned ex post to the party that values it the most. Unlike the incentive approach, the value approach produces implications for comparative variation once one recognises the importance of transaction costs and heterogeneous moral values. Due to the prevalence of transaction costs, most transactions occur through intermediaries. Moral norms are heterogeneous within jurisdictions and hence some intermediaries are honest, while others are willing to steal and resell the good. Honest intermediaries can only operate in markets in which buyers value goods more than their original owners and hence there is scope for trade. Dishonest intermediaries also prefer such markets because they are characterised by higher resale prices. It follows that, on average, buyers value goods more than their original owners do and, hence, the ownership of stolen goods should in principle be assigned to buyers. Yet, societies differ in their moral norms and the strength of their law enforcement and hence implement this criterion in different degrees: these differences immediately imply a sharp empirical prediction on the determinants of comparative variation.

35 A possible objection to this argument is that, in an efficient market, owners who have not sold their goods must value them more than buyers. Hence, dishonest intermediaries transfer goods from a high-valuing to a low-valuing party. Yet, this is only true if market transactions take place before theft. In reality, instead, both honest and dishonest intermediaries operate simultaneously in the market, so that it is not plausible that all dispossessed owners have a high valuation of the good.
C. How Self-Reliance Affects Law

On the one hand, in jurisdictions with stronger enforcement and efficient courts, protecting the buyer is more relevant than in other jurisdictions. This is because stronger enforcement makes owner protection a relatively effective way to transfer goods back to their original owners. This is undesirable; hence, the greater the strength of enforcement in a jurisdiction, the greater the probability of observing buyer protection. On the other hand, in jurisdictions with a strong culture of morality, there is less propensity to steal; hence, relatively few goods on the market are stolen and it becomes less desirable to protect buyers. Thus, the lower the level of trust and respect, the greater the probability of observing buyer protection.

Table 2 illustrates these predictions by building on the four representative jurisdictions we use as examples: countries with a stronger culture of morality but weaker enforcement have stronger owner protection than countries with weaker norms of trust and respect but stronger law enforcement. Given the definition of self-reliance we gave in the Introduction, the effects of a culture of morality and the strength of enforcement on law can be condensed into the following testable hypothesis:

Hypothesis: A higher degree of self-reliance is associated with a higher level of owner protection.

Looking again at Table 2, self-reliance is indeed high in the bottom-right box and low in the upper-left box, while it takes an intermediate value in the other two boxes. The quest for different optimal rules for different jurisdictions sets our approach apart from the vast literature on good faith purchase, which generally tries to identify the rule that is most desirable for all legal systems.36

---

36 Landes and Posner (n 5); Weinberg (n 32); Ben-Shahar (n 33); Schwartz and Scott (n 4). Exception are Levmore, ‘Variety and Uniformity’ (n 3); Reyhan (n 5) 955; Lehavi and Licht (n 20).
In contrast, our inquiry is based on the idea that each jurisdiction selects a desired level of owner protection depending on its cultural characteristics. Since each owner was at some point in the past a buyer and each buyer becomes an owner after the purchase, society (consisting of all potential owners and buyers) is likely to choose the legal rule behind a veil of ignorance, which is, not knowing which role an individual will have once the ownership of stolen goods is assigned. Thus, society is most likely to advance social welfare by maximising the ex post value of goods rather than catering to the specific interests of either owners or buyers. In the following, we will show that the relationship between self-reliance and owner protection empirically holds in our large sample of countries and will contrast our hypothesis with four dominant theories of comparative variation. In the analysis, we focus on the most salient index of bona fide purchase through a private sale, yet, our results are similar for the general term of adverse possession in good faith and for other sale environments (see Appendix). Before proceeding we address two preliminary issues.

The fact that the owner might have to compensate the buyer upon reclaiming the good does not change our conclusions. In fact, to the extent that compensation perfectly matches the buyer’s valuation of the good, owners will rarely reclaim the good because, as we have explained, buyers typically value the good more than original owners and hence the owner compensation will typically exceed the owner’s willingness to pay. Compensation, however, will often be less than the buyer’s valuation; for instance, some jurisdictions in our sample require that the owner pay the purchase price, which will typically be lower than the buyer’s valuation. If this is the case, owner protection results in an undesirable transfer of the good to a lower-value user. In conclusion, compensation equal to the buyer’s valuation counters the effect of owner protection but, in reality, compensation is typically imperfect. In both cases, our results remain valid.

An additional factor that might be relevant is the effect of good-faith purchase rules on the value of goods for owners and buyers. Since buyer protection prevents dispossessed owners from reclaiming their goods and might make thieves more aggressive, implementing buyer protection might reduce the security of ownership and hence the value owners attach to their goods. Yet, the same effect would occur for buyers since they become owners after the purchase. Therefore, both the valuation of owners and buyers will simultaneously change due to a change in the rule. Since our analysis is based on a comparison between the owner’s and the buyer’s valuation, our results remain valid.

37 The index on statutes of limitations is largely irrelevant for the statistical analysis in that either its length exceeds the terms for adverse possession or acquisitive prescription or because it starts running only after the owner locates the stolen good. See Schwartz and Scott (n 4) 1336–37. In a few cases, when the statute of limitations is relevant, the index on good faith purchase of stolen goods already includes consideration of it. The data on compensation and on the definition of good faith deliver similar results.
D. Culture, Language and Law

More secure property rights for the original owner and, in turn, a lower incidence of theft might, on the one hand, reinforce norms of trust and respect and, on the other, relax the need to enforce the law. Because of this plausible reverse causality issue, the results summarised in Figure 2 might appear weaker than they really are or, even worse, they might be spurious. To address this problem, we rely on basic features of languages, pronoun usage, to identify the impact of culture on the law. These grammatical features persist for centuries so that it is hard to envision any dependence on private law rules. Moreover, motivated by a theory known as the Sapir-Whorf Hypothesis on the connection between language and cognitive processes, a large literature in linguistics and anthropology has verified empirically that language modulates the way in which individuals see and interpret the world and hence affects the prevailing culture. As a consequence, the features of the language spoken by the plurality group in a jurisdiction can be used to capture exogenous and long-lived components of culture. Two culturally relevant features of pronoun usage in different languages have been identified by Emiko Kashima and Yoshihisa Kashima: ‘pronoun drop’ and ‘pronoun difference’. Concerning the first feature, some languages, such as Italian and Turkish, allow the speaker to drop the first person pronoun next to a verb—that is, one can say ‘go’ instead of ‘I go’—while other languages, such as Danish and French, do not allow such usage. The possibility of dropping the first-person pronoun

38 E Sapir, Language (Harcourt 1921); BL Whorf, Language, Thought, and Reality: Selected Writings of Benjamin Lee Whorf (J-clear ed, MIT 1956). Skepticism toward the Sapir–Whorf Hypothesis derives from the idea that languages are manifestations of a uniform innate ‘universal grammar’ and hence cannot shape the speakers’ ways of thinking; N Chomsky, Syntactic Structures (de Gruyter 1957); S Pinker, The Language Instinct: How the Mind Creates Language (William Morrow 1999). On the cultural role of language see M Douglas, Natural Symbols (Barrie and Rockliff 1970) and B Bernstein, Class, Codes and Control (Routledge 1971).

40 See C Chiu, ‘Language and Culture’ (2011) 4(2) Online Readings in Psychology and Culture 2015 for a review of studies documenting the effect of language on culture. In particular, studies on bilingual subjects have found that behaviour is affected by the language used in the experiment (ibid 6–7).

attributes less prominence to the self in the discourse and prompts weaker norms of trust and respect for individuals outside the family circle. Kashima and Kashima explain this relationship very clearly:

the linguistic practice of pronoun drop, particularly the omission of the first-person singular pronoun (eg ‘I’ in English), is linked to the psychological differentiation between the speaker and the context of speech, including the conversational partner. An explicit use of ‘I’ (ie first-person singular deictic pronoun) signals that the person is highlighted as a figure against the speech context that constitutes the ground; its absence reduces the prominence of the speaker’s person, thus reducing the figure-ground differentiation.

[Therefore,] languages licensing pronoun drop are associated with lower levels of Individualism than those that require the obligatory use of personal pronouns such as ‘I’ or ‘you’ as a subject of the sentence.44

Kashima and Kashima show that jurisdictions where the plurality group speaks a language that does not license pronoun drop are associated with a culture of individualism. Indeed, ‘[s]ocieties whose cultures emphasize individual uniqueness and view individual persons as moral equals are likely to develop norms that promote societal transparency as a means for social coordination’ and, hence, are characterised by high levels of trust and respect for others.45

Concerning the second feature, in some languages, such as Italian and French, there are two (or more) different second person pronouns, one for formal and one for informal contexts, such as ‘ye’ and ‘thou’ in early English, suggesting social distance and regard for hierarchy. In other languages, such as Danish and Turkish, these differences do not occur. Kashima and Kashima explain this point as follows:

Earlier in history a higher status person called a lower status person by T, whereas the lower status person addressed the higher status person by V. More recently, however, equal status people call each other by T or V depending on their intimacy; the T of intimacy and the V of formality. In other words, the T–V differentiation was used to index power difference before, but more recently is used to index social distance. To use the T–V distinction appropriately, the speakers must pay close attention to the type of their interpersonal relationships with their addressees. In contrast, the use of present-day English, which has only one 2PS [second person] pronoun, you, does not require the speaker to hold or attend to such information…Thus, a language with multiple 2PS pronouns implies, relative to a language with only one 2PS pronoun, a conception of the self–other relationship that is structured by social distance, such as power differentiation (ie status hierarchy) and ingroup–outgroup differentiation (ie differentiation between insiders who are close and outsiders who are distant.46

43 See for this definition J-P Platteau, Institutions, Social Norms, and Economic Development (Routledge 2000).
44 Kashima and Kashima, ‘Culture and Language’ (n 42) 465 and 477 (footnotes omitted).
45 Licht, Goldschmidt and Schwartz, ‘Culture Rules’ (n 41) 663.
46 Kashima and Kashima, ‘Culture and Language’ (n 42) 467 (footnotes omitted). See also P Mühlhäusler and R Harré, Pronouns and People: The Linguistic Construction of Social and Personal Identity (Blackwell 1990) 139.
Again, Kashima and Kashima demonstrate that jurisdictions where the plurality group speaks a language licensing pronoun difference are associated with a culture of regard for hierarchy. Indeed, societies that ‘view the individual as an embedded part of hierarchically organized groups... are more likely to accommodate exercise of power from above’ and hence condone a stronger centralised enforcement. 47

The empirical results by Kashima and Kashima allow us to use features of pronoun usage to classify countries along two cultural dimensions. Countries whose languages use both pronoun drop and pronoun difference (for instance, Italy) exhibit lower levels of trust and respect for the individual and higher regard for hierarchy than countries with no drop and no difference (such as Denmark). France and Turkey fall somewhere in between these two extremes, as they score high on one measure and low on the other: French allows for pronoun difference but not for pronoun drop, while Turkish allows for pronoun drop but not for pronoun difference. Table 3 illustrates this point and shows how language features are related to owner protection in the four countries that we use as examples.

Notably, Table 3 illustrates the correlations described at the outset: trust and respect, as measured by pronoun drop, are positively related to owner protection, while the strength of enforcement, as measured by pronoun difference, is negatively related to it. Most importantly, using pronoun usage to measure these two cultural features makes us confident that we are not picking up an effect of law on culture rather than the opposite.

As anticipated above, to simplify the interpretation of the results, we summarise the two language features in our self-reliance variable. This variable takes a value equal to 1 if both features are present, 2 if either of the two is present, and 3 if none of them is present. This definition implies that a language scoring lower on self-reliance more easily accommodates power from above and puts less focus on being trustworthy and respectful with strangers. 48

48 In our data, the Spearman correlation coefficients between self-reliance and our measures of trust and respect are 0.27 and 0.28 respectively. On the contrary, the Spearman correlation coefficient between self-reliance and our metrics of enforcement is –0.11.
Evaluating Causality: A Case Study

Guido Tabellini has argued that language evolves slowly over time, almost certainly more so than values. Moreover, the two grammatical rules on the use of pronouns capture deep and stable features of the language (this is particularly true of the rule forbidding pronoun drop). Hence, there is little doubt that they are correlated with distant cultural traditions, rather than with more recently acquired traits. Thus, using Language as an instrument for values, we have taken care of the problem of reverse causation.49

Yet, in the long run languages are also endogenous, since they adapt to the environment and the communication needs of their speakers. For instance, both English and Polish varied their use of pronoun difference over time but in opposite ways. In the 14th century, Polish had no pronoun difference, but English did. In contrast, the current usage allows pronoun difference in Polish but not in English.50

The languages, cultures, and legal systems of nation states with long histories (for instance, England) developed simultaneously. Moreover, former colonies of European powers have often received both language and law from the coloniser. Therefore, although language is considered by many scholars a determinant of culture and law,51 it is crucial to establish that the relationship we find between language and law is causal. The history of Italy, Scandinavia, Eastern European countries (for instance, Poland), and some near Asian countries offers a nice case study for our claim regarding causality.

These countries did not have a history of independent nation statehood before 1815.52 To elaborate, they were part of the Russian, Austrian or Ottoman Empire or existed under the kingdoms of Prussia, Denmark or Sweden. These powers crumbled in the 19th century or were wiped out by World War I, at the end of which national borders were drawn according to an ideal of ethnic homogeneity.53 A new wave of decomposition into smaller nation states followed the fall of the Soviet Union, Yugoslavia and the Eastern Bloc. Italy followed a different path, acquiring independence by means of unification. Therefore, all of these newly independent nations chose their modern legal systems after 1815, and most of them at a much later date after the end of World War I or the fall of the Berlin Wall. At that time, the basic features of the language spoken by the majority of the population had most

52 We consider Belarus, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, Czech Republic, Estonia, Finland, Georgia, Greece, Hungary, Italy, Kosovo, Latvia, Lithuania, Montenegro, Norway, Poland, Romania, Serbia, Slovakia and Slovenia. For Albania, Armenia, Azerbaijan, Macedonia, Moldova and Ukraine we do not have data on either languages or the law.
likely already crystallised in the form that we know today. For instance, accurate data are available for English and Polish. ‘Thou’ and ‘ye’ in written English had been displaced by ‘you’ by the mid-17th century.54 Similarly, Polish had already acquired the current pronoun usage by the mid-15th century.55

Figure 5 shows the levels of self-reliance in the 22 countries that we consider here and contrasts them with the level of protection afforded to owners versus good faith buyers in private sales. As the theory predicts, a higher level of self-reliance corresponds to a higher level of owner protection. This is particularly evident in Norway, Finland, Slovakia, Italy, Croatia and Belarus. Most of the remaining countries have low levels of self-reliance but exhibit intermediate levels of protection. Yet, in all but two cases (Estonia and Greece), the buyer acquires ownership in three years (five years in Estonia). Therefore, even if protection is classified as intermediate, in fact it is very close to buyer protection, which corresponds nicely with the low levels of self-reliance. The Czech Republic and Hungary have intermediate levels of self-reliance but exhibit pure owner protection, confirming the trend even if not perfectly matching it. Cyprus, Serbia, Montenegro and Kosovo are not in line with these trends; however, other determinants of comparative variation could explain these differences. In over four-fifths of the cases considered here, countries with a predetermined endowment of culture as captured by their crystallised language moved toward an optimal level of owner protection after gaining independence. The evidence provided by this case study supports our claim that the correlations we find are not due to reverse causality.

3. Empirical Analysis

To test the explanatory power of self-reliance versus other theories of comparative variation we employ regression analysis. In each of the regressions reported in Table 4, we consider the effect of two explanatory variables on our index of owner protection in private sales. One explanatory variable is always self-reliance, while the other one changes across regressions, so that each regression considers a different factor borrowed from an alternative theory of comparative variation. Thus, each regression tests whether cross-country variation in owner protection is statistically related to variation in self-reliance.

54 We have gathered this information from two comprehensive online databases. The Google Books Ngram Viewer <http://books.google.com/ngrams> tracks the usage frequency of words in a corpus of over 5 million digitalised books, corresponding to approximately 4% of all books ever published; see J-B Michel and others, ‘Quantitative Analysis of Culture Using Millions of Digitized Books’ (2011) 331 Science 176. The Corpus of Historical American English <http://corpus.byu.edu/coha> contains 400 million words of text of American English from 1810 to 2009 and shows a further sharp decline in the use of ‘thou’ after 1810. Both databases were accessed on 26 November 2012. See also AH Jucker and I Taavitsainen, ‘Introduction’ in AH Jucker and I Taavitsainen (eds), Diachronic Perspectives on Address Term Systems (John Benjamins 2003) 1, 5 (arguing that ‘thou’ had virtually disappeared in Britain by 1700).

Figure 5. Owner Protection in Private Sales (left) and Self-reliance (right) in 22 Young Legal Systems
or to variation in the alternative factor, that is, it tests whether self-reliance explains comparative variation better than an alternative theory.

For each of the two explanatory variables the regression analysis returns two crucial pieces of information that we will use in the following sections: a coefficient and a \( p \)-value. The coefficient measures the effect of the explanatory variable on owner protection. A large absolute value of the coefficient suggests that that variable explains a large part of the variation in bona fide purchase rules. The sign of the coefficient indicates whether an increase in the value of the explanatory variable is related to an increase (positive sign) or decrease (negative sign) in owner protection. However, in a large dataset, variables could be related to each other by chance. The \( p \)-value is the probability of obtaining the observed distribution of data given that the coefficient is equal to zero. If lower than 1% (three asterisks in the table), there is very low chance that a coefficient equal to zero has spurred the observed variation and we can reject at this confidence level that the coefficient is null and, consequently, that the results of the regression analysis are due to chance. We also consider two other less stringent confidence levels: 5% (two asterisks) and 10% (one asterisk). If a coefficient is not statistically significant (no asterisk), the corresponding explanatory variable fails to account for variation in owner protection.

In the Appendix we provide the definition, source and summary statistics of each variable plus some additional statistical analysis, as well as additional robustness checks. In each of the following subsections, we will introduce a

or to variation in the alternative factor, that is, it tests whether self-reliance explains comparative variation better than an alternative theory.

First, we document that our conclusions are similar when we regress our different measures of owner protection on the proxies for a culture of morality and the quality of law enforcement. Second, we show that these results remain stable when we use the full-form 2SLS, ie first regress each of our proxies for culture and
theory of comparative variation, illustrate its empirical implications, explain how we measure its relevance and discuss the results of our test as reported in Table 4.

A. Functional Equivalence Versus Self-Reliance

Konrad Zweigert and Hein Kötz authoritatively propose that formally different legal rules often reach the same results in practice.\(^\text{57}\) Thus, comparative variation needs to be assessed not on the basis of superficial differences between formal rules, but by looking at the deeper differences in the effects that those rules have on behaviour. Thus, a long tradition of comparative law studies seeks to understand how different legal systems deal with the same factual situations.\(^\text{58}\) In our case, the factual question is which party—the owner or the buyer—can recover or retain the good.

The main empirically testable implication of the functional equivalence theory has been put forward by Saul Levmore, who argues that most differences among legal systems can be rationalised as noise: the question is so subtle that most people would have different opinions as to which solution is best. Thus, while it is clear that theft should be punished and hence we observe uniformity in the punishment of theft across countries, it is less clear whether the owner or the buyer should recover or retain a stolen good, and hence we observe comparative variation.\(^\text{59}\) This claim is based on the underlying idea that legal systems tend to develop a single efficient rule to deal with similar problems;\(^\text{60}\)

59 Levmore, ‘Variety and Uniformity’ (n 3) 44–45. U Mattei, ‘Efficiency in Legal Transplants: An Essay in Comparative Law and Economics’ (1994) 14 Int’l Rev L & Econ 3 attributes comparative variation to legal parochialism, which could be viewed as a form of random disagreement on the best outcome. Yet this does not bring our approach to overlap with the functional equivalence approach since the question remains whether culture causes random noise or, as we claim, predictable effects on the law.
hence, there is a natural tendency toward convergence even absent any direct reciprocal influence.61

This clear empirical implication does not necessitate the identification of the efficient outcome. Since different rules are accounted for as quasi-random variations around the efficient solution (whatever that may be), differences among legal systems should emerge as random noise in a large sample of countries and, in particular, should not be correlated with a country’s culture of morality. The functional equivalence theory predicts that differences should appear in the data as random noise with no particular pattern. In contrast with this prediction, we find that self-reliance enters the analysis with a positive and significant coefficient in each of the regressions in Table 4, which shows that comparative variation is not random noise and, to the contrary, is correlated with self-reliance.

B. Legal Origins Versus Self-Reliance

The transplants theory, most frequently associated with Alan Watson, explains differences among legal systems as transplants from one system to another.62 The underlying idea is that rules spread through direct contact between legal systems. According to Zweigert and Kötz, since most differences are in fact functionally equivalent, formal differences tend to persist.63 This approach has also pervaded a long tradition of studies in political science and economics, although often under quite different guises. A taxonomy is best provided according to the channel through which transplants occur. The most fundamental manifestation of the transplants theory is the legal families

---

61 Murray (n 5) 24; Mattei, ‘Efficiency in Legal Transplants’ (n 59) 16; Zweigert and Kötz (n 57) 39; U Mattei, Basic Principles of Property Law (Greenwood 2000); M Kovac, Comparative Contract Law and Economics (Elgar 2011).
theory in comparative law, also known as legal origins theory in comparative economics, according to which the primary channel for transplants was colonisation. Thus, legal systems around the world are traditionally classified according to the family of origin, that is, whether they inherited common law or one of the varieties of civil law from a coloniser. This view tends to dichotomise a past in which differences somehow originated and a present in which differences are spread through transplants. Economists have derived from it a clear empirical prediction: current differences among different countries can be largely explained by the common–civil law divide.

Another strand of the transplants theory allows for transplants in recent times and justifies them as borrowing from ‘prestigious’ systems. However, the notion of prestige can be carefully defined only when looking at specific cases of borrowing and does not easily lend itself to empirical testing in a large sample of countries. Yet another strand of the transplants theory views convergence as the result of competition among jurisdictions and has been pioneered by Roberta Romano. If law is seen as a ‘product’, then competition forces less valuable rules out of the market—or, more precisely, out of the law books—and in the long run only the most efficient rules will survive. However, this theory does not require the surviving rules to be efficient. In fact, it admits both a race to the top and a race to the bottom. In both cases, it predicts a large degree of uniformity and allows divergence only as the result of product differentiation, temporary disequilibrium due to experimentation or, more generally, random noise. Similar implications follow from diffusion studies,
which view legal innovation as akin to technological and commercial innovations and hence look at the diffusion paths of novel doctrines.\textsuperscript{72}

The jurisdictional competition and diffusion theories do not provide attractive explanations for comparative variation in that they mostly predict convergence toward a uniform rule or a variation as a result of quasi-random factors, which we discussed in subsection A.\textsuperscript{73} The legal origin theory, as recently stated by Rafael La Porta, Florencio Lopez de Silanes and Andrei Shleifer,\textsuperscript{74} instead predicts that comparative variation should be explained by the common law versus civil law origin of the system.\textsuperscript{75} Yet looking at the legal family of a country at the moment of independence has two main drawbacks. First, it could capture whether the coloniser was Britain or another European power and hence confound information about legal institutions with other changes that the experience of colonisation might have brought about—not least things like business culture, language and religion. Second, recent evidence shows that many jurisdictions have reformed their legal systems after colonisation.\textsuperscript{76} Accordingly, we classify jurisdictions along a civil–common law continuum by focusing on legal institutions in place today rather than at the time of colonisation. These measures comprise the following: (i) whether appellate decisions have precedential value; (ii) whether appeals are granted purely on issues of law or also on facts; (iii) whether judgments can be based on equity; (iv) whether procedure is adversarial; and (v) whether evidence is mostly submitted orally. If all these characteristics are present, the system can be classified as a pure common law system.\textsuperscript{77} Hence, our continuous measure allows for a classification of countries based on their degree of proximity to a pure common law system. If the common–civil law divide has an effect on private law, we should be able to detect it in the data.

\textsuperscript{73} See for instance BH Kobyashi and LE Ribstein, ‘Evolution and Spontaneous Uniformity: Evidence from the Evolution of the Limited Liability Company’ (1996) 34 Econ Inquiry 464 (studying the evolution of the limited liability company); Ogus, ‘Competition Between National Legal Systems’ (n 1) (distinguishing between situations in which preferences over the law are homogeneous and convergence is likely and situations in which preferences are heterogeneous and convergence is unlikely).

\textsuperscript{74} La Porta, de Silanes and Shleifer (n 66).

\textsuperscript{77} JH Merryman, The Civil Law Tradition (Stanford University Press 1969); Zweigert and Kötz (n 57); MA Glendon, PG Carozza and CB Picker, Comparative Legal Traditions in a Nutshell (Thomson 1999).
In order to contrast our cultural explanation with the legal origins explanation, we use a simple test. We are interested in verifying to what extent a common law origin can explain owner protection once we account for the effect of self-reliance. The first column in Table 4 shows that the coefficient attached to common law is positive but insignificant, whereas the coefficient on self-reliance is positive and significant. This suggests that, once we account for the effect of self-reliance, common law is not a good predictor of comparative variation in owner protection.

C. Political Economics Versus Self-Reliance

A third very prominent approach to comparative variation not only in private but also in constitutional law views politics as a key determinant of the evolution of legal rules.78 Powerful elites or political majorities might design the law to their advantage and hence differences across countries can be traced back to political conflict.79 Rules that favour minorities only emerge as concessions due to the need to provide incentives to take part in economic activities or for fear of revolution.80 Exogenous shocks can unbalance power and prompt institutional discontinuities; for instance, Mark Roe has argued that politics, not legal origin, explains differences in corporate governance across the world.81 We consider two main political variables that could have an impact on the law: the strength of democracy and the nature of the electoral system (proportional versus majoritarian). In weaker democracies, powerful minorities can concentrate power and exploit the majority. In the context of our analysis this could imply that (at least initially) more politically powerful owners could obtain more legal protection of their property against theft.82 Thus, the level of owner protection should be inversely correlated with the level of democracy.

81 Roe (n 67). Another strand of literature has argued that centralised systems emerge to counter private coercion by powerful elites, see E Glaeser and A Shleifer, ‘The Rise of the Regulatory State’ (2003) 41 J Econ Lit 401. In our analysis, self-reliance is not connected to private coercion but rather to the propensity to enforce the law and a culture of morality. Moreover, our analysis considers private expropriation—the involuntary transfer of the owner’s property to an innocent buyer by a thief or another intermediary without legal power to do so—which is different from private coercion.

82 See C Guerriero, ‘Endogenous Property Rights’ (manuscript on file with the authors 2014).
The nature of the political system could also affect the law. As shown by Marco Pagano and Paolo Volpin, politicians in proportional systems tend to cater to the preferences of large constituencies while in a majoritarian system they go after the votes of pivotal groups. Hence, we would expect majoritarian systems to protect the concentrated interests of owners and proportional systems to be more open toward buyer protection.

An alternative hypothesis, which supports our cultural explanation, is that the roles of buyers and owners are normally interchangeable in a market setting, since owners were once buyers and buyers will become owners. Therefore, both owners and buyers should support rules that maximise total welfare or, stated otherwise, that cater to their interests behind the veil of ignorance, that is, before knowing whether they will be good faith buyers or dispossessed owners of stolen goods. From this perspective, both democracy and the electoral system should have no effect on owner protection.

To test the political economics theories against our cultural explanation, we employ the same procedure as in the previous section. We first examine democracy as measured by the constraints on the executive as coded in the Polity IV dataset, averaged over all available years. As the second column of Table 4 shows, democracy does not have a statistically significant impact on owner protection whereas self-reliance does.

We now turn to the electoral system as an explanatory variable. We use the data collected by Lorenz Blume, Jens Müller, Stefan Voigt and Carsten Wolf on the electoral systems in force in a subset of our jurisdictions. The third column of Table 4 confirms the crucial role of self-reliance and shows that majoritarian electoral systems have a small and only marginally significant impact on owner protection. This effect goes in the expected direction.

D. Self-Reliance Versus Religious Beliefs

The importance of culture for law and economic activities is the theme of a burgeoning literature. A powerful determinant of cultural traits and their
diffusion is religion. A very influential theory proposed by Max Weber points to Protestantism as the determinant of a capitalistic attitude. According to Weber, Protestantism removed the assurance of salvation, which had been guaranteed by the Roman Catholic Church to those who accepted sacraments and recognised the authority of the clergy, and submitted it to worldly success. At the same time, Protestantism discouraged luxury and seriously limited icons and decorations in churches and charity to the poor, which was seen as encouraging begging. As a result, the Protestant ethic encouraged work and discouraged spending, channelling the proceeds of labour into reinvestment.

The effect of religion on markets has been observed empirically; in particular, Stulz and Williamson show that Protestant countries exhibit higher levels of creditor protection than Catholic countries. This is related to the Protestant view that interest is a normal part of commerce. Accordingly, their data shows a higher level of creditor protection in Protestant countries. In relation to the good faith purchase of stolen goods, Protestantism should have important effects on how private property is regulated and in particular should induce more owner protection. More precisely, a larger share of Protestants in a country should be a good predictor for a higher level of owner protection.

Yet culture is not a monolithic phenomenon. Lehavi and Licht have proposed individualism as a cultural feature that affects the protection of (both physical and intellectual) private property. In less individualistic countries, people are more strongly embedded in a social context and hence private property is more loosely protected. It is therefore natural to inquire into the effects of different cultural features on the property–contract balance. In particular, we will compare the explanatory power of religion and self-reliance, which encompasses individualism as one of its two subcomponents.

To test the effect of Protestantism on owner protection we again employ the same empirical strategy. We use data from a study by Rafael La Porta, Florencio Lopez-de-Silanes, Andrei Shleifer and Robert Vishny reporting the share of the population belonging to the Protestant religion in 1980 in each country. As the fourth column of Table 4 shows, the effect of Protestantism on owner protection is not statistically significant whereas the coefficient
attached to self-reliance is still positive and highly significant. This result supports the view that culture is a multidimensional phenomenon, so that a specific characteristic of a legal system might be explained by a particular cultural trait while being independent of another. In turn, this reinforces our approach, which is grounded in the notion of self-reliance, capturing the two different and rather independent cultural traits of individualism and regard for hierarchy.

4. Conclusion

Our analysis shows that comparative variation in good faith purchase rules can be traced back to deep cultural differences among countries and, in particular, different levels of self-reliance. We have shown that self-reliance fits the data better than alternative theories based on functional equivalence, legal origins, political economics, and religion, an alternative measure of culture. Our results should be appreciated within the limits of our empirical analysis. Our data concern a specific legal issue and hence do not imply that self-reliance should be embraced as the only determinant of comparative variation in all areas of the law. Quite the opposite, the evidence accumulated by the literature that we discuss suggests that comparative variation might be explained by different factors in different areas of the law. Furthermore, we did not attempt to test all theories of comparative variation. The need to feed the analysis with reliable data limits the scope of any empirical analysis. Although we believe that we have identified four widely representative approaches, as more data becomes available, more complete tests will be possible. Finally, our measure of cultural differences is limited to self-reliance, which was not meant to capture all cultural differences among countries. To the contrary, we have shown that different measures of culture—we used one measure based on self-reliance and another based on religion—have different effects on the law. Culture is a multifaceted phenomenon and there are many ways to quantify cultural differences. The approach we chose is not a superior description of culture in absolute terms but it fits the data on the good faith purchase of stolen goods better than the alternative we considered.

Going further, our results naturally produce a hypothesis on the diachronic evolution of good faith purchase rules. In Western countries, the baseline rule was the pure owner protection inherited from the Roman law maxim stating—in its modern formulation—that *nemo dat quod non habet*. This principle was slowly abandoned during the Middle Ages to give more room for the protection of buyers, especially for purchases effected in specified markets. This process raises the question of why and how the divergences that we now observe in modern law originated. Can they be rationalised as responses to changing cultural contexts? One view is that the development of impersonal markets brings with it a decrease in the levels of mutual trust and respect as it
attracts foreigners who do not share the same values as the community hosting and regulating the markets. Moreover, market transactions are more transparent than private exchanges and should therefore ease law enforcement. These considerations suggest that divergence might have originated as a response to the certainly inhomogeneous distribution of markets across Europe. Yet, these conjectures require further historical research. In particular, it would be interesting to be able to track the changes in good faith purchase rules and to link them to specific historical events.

Finally, our analysis has implications for the current process of legal harmonisation. Understanding the causes of comparative variation is a fundamental precondition for discussing harmonisation. It is a truism that to decide whether two countries should have the same rules, one should first understand why they have different rules. Different views of comparative variation suggest different harmonisation policies. If comparative variation is due to random noise, getting rid of it has the advantage of sparing the cost of legal uncertainty. If instead comparative variation is an optimal response to different cultural backgrounds, pushing harmonisation induces countries to deviate from their ideal rules and hence brings about large losses. Our analysis speaks against the unqualified elimination of legal differences and casts a vote for a central role of comparative legal scholarship even in a world of increasing legal harmonisation.
