A π-electron deficient diaminotriazine functionalized MOF for selective sorption of benzene over cyclohexane†

Biplab Manna,‡a Soumya Mukherjee,a Aamod V. Desai,‡a Shivani Sharma,a Rajamani Krishnaa and Sujit K. Ghosh*a

A diaminotriazine functionalized novel MOF (DAT-MOF-1) has been synthesized stemming out of a π-electron-deficient pore-surface functionalization based linker-design principle, which results in efficient selectivity of benzene sorption over its aliphatic analogue cyclohexane, crucial from the industrial standpoint.

Metal–organic frameworks (MOFs), formed by the coordination chemistry-assisted self-assembly process of organic linkers and metal ions, have evolved as one of the most preferred new-generation materials, owing to their superlative potential in multifarious fields, such as gas storage, chemical separation, sensing, drug delivery, and catalysis.1 These crystalline materials score over the other classes of functional materials because of a few unique advantages, such as their unique periodical structures with long-range order, excellent porosity, framework flexibility, and tunable pore surface functionalization, which endow them with promising storage and separation applications.2 Among the diverse porous adsorbent materials utilized for serving efficient separation of flue gas and hydrocarbons, MOFs have established themselves as a uniquely promising class of functional adsorbents owing to the unmatched unison of their aforementioned characteristics.3

From the application perspective, the separation of liquid phase hydrocarbons, especially those having similar physical properties and comparable molecular sizes, is highly challenging for industrial applications. In this context, the industrially crucial separation of benzene (Bz) and cyclohexane (Cy) poses a challenge. The recognized difficulty behind this C6 hydrocarbon stream separation originates as a consequence of the unavoidable production of cyclohexane during the catalytic hydrogenation of benzene in the benzene/cyclohexane miscible system and also due to their considerably close boiling points (benzene, 353.25 K; cyclohexane, 353.85 K: Table S1, ESI†), similar molecular volumes, comparable Lennard-Jones collision diameters along with low relative volatilities.4 While close proximity in their boiling points (difference: 0.6 K) rules out conventional fractional distillation methods, specialized distillation protocols such as azeotropic and extractive distillation methods employed with entrainer species such as sulpholane, dimethylsulfoxide, N-methylpyrrolidone, and N-formylmorpholine involve high energy-intensive requirements. On the contrary, adsorptive separation offers an energy-efficient alternative to extractive distillation, especially for Bz/Cy mixtures containing small percentages of benzene, as is commonly encountered.

Interesting enough, these two analogue species have distinct spatial configurational orientations; benzene is a planar π-cloud entity, while aliphatic cyclohexane exists in either chair or boat configuration (Fig. S1, ESI†). This inherent dissimilarity might seem to be the imperative key factor behind efficiently separating the duo (Scheme 1). The favourable role of π-complexation with benzene behind the selective sorption-mediated Bz/Cy separation was explored in cation-exchange Faujasite-type zeolites Na-Y, Pd-Y, Ag-Y, and FAU-type zeolite membranes;5 while

recent years have witnessed some porous MOF materials being used for the targeted selective sorption based separation of Bz/Cy. However, the ligand design-strategy derived achievement of such separation performance is indeed scarce.

Ligand functionalization based attainment of excellent separation performance by MOFs has witnessed remarkable upsurge in recent times, markedly motivated by the pioneering work of Chen et al. Over the years, the triazine core has been quite well-harnessed chiefly by Zhou et al., as constituent linkers in the MOF domain for presenting excellent adsorption features with concomitant thermal robustness of the materials. Under this backdrop, we intended to achieve Bz/Cy separation by the favourable π–π stacking driven interplay of the π-electron deficient triazine core of the employed rigid carboxylate linker (Fig. 1) functionalized MOF pore surface and π-rich guest species benzene. Herein, for the first time, the electron deficient dianimotriazine (DAT) core of a new-fangled rigid mono-functionalized 3D-framework, the pores along the a-axis (Fig. S11–S14, ESI†) of dimensions ~6.71 × 7.08 Å² are well-decorated with Lewis basic primary amino groups, imparting framework functionalization.

In the asymmetric unit from Fourier maps in the refinement cycles, because of a high extent of disorder for these moieties in the crystal. The phase purity for the as-synthesized phase was confirmed by the PXRD analyses (Fig. S18, ESI†) coupled with the SC-XRD-based unit cell analysis of arbitrarily chosen crystals from the bulk phase.

As observed from the perspective view of the supramolecular H-bonded 3D-framework, the pores along the a-axis (Fig. S11–S14, ESI†) of dimensions ~6.71 × 7.08 Å² are well-decorated with Lewis basic pyridyl and primary amine functionalities, which should ideally facilitate strong interactions with polar guest species CO₂ owing to the latter’s high quadruple moment (~13.4 × 10⁻⁴⁰ C m³)¹⁰ over its congener flue gases. The anticipated CO₂-selective adsorption feature was indeed verified for the activated form of DAT-MOF-1a, namely DAT-MOF-1, as evident from the single component gas adsorption isotherms recorded at low temperatures (77 K and 195 K). Exclusively for CO₂, there was a distinct two-step-mediated adsorption uptake observed with noteworthy hysteresis (typical signature of dynamic frameworks) (Fig. S20, ESI†), owing to the concomitant host-guest interaction-driven dynamic structural transformations or breathing phenomena, accompanying the CO₂ vapour sorption process. A prominent two-step sorption profile and the observed hysteretic desorption can be attributed to structural transitions between relatively open and closed framework structures as CO₂ adsorptive gets adsorbed with substantial hysteresis consequential from the metastability of the more open structure, similar to the previous reports on breathing phenomena exhibited by soft porous crystalline frameworks. On the flipside, no such steps were observed for the CO₂ sorption isotherm at 298 K over a similar pressure range (Fig. S21, ESI†), validating the dependency factor of the structural transitions accompanying the sorption process on the low temperature-mediated specific interactions of the host framework with guest CO₂ molecules. The guest-free nature and excellent crystalline features of the activated phase DAT-MOF-1 were once confirmed from the thermogravimetric analyses (TGA) and Powder X-ray Diffraction (PXRD) profiles respectively.
Substantiating the anticipated selective interplay of Bz with DAT-MOF-1, the single component vapor sorption experiments for both the solvents Bz and Cy when measured at 298 K, the striking difference between their respective uptake amounts (1.5 mol kg$^{-1}$ for Bz, while only 0.2 mol kg$^{-1}$ for Cy) was revealed (Fig. 3 and Fig. S22, ESI†). $^{13}$C NMR studies performed using the DCI/DMSO-$d_6$ digested samples after vapor exposure to the Bz and Cy solvent vapors and their 1:1 equimolar mixtures indubitably revealed exclusive Bz-selectivity (Fig. S23, ESI†).

We evaluate Bz/Cy separation by utilizing the Ideal Adsorbed Solution Theory (IAST) calculations. Fig. 4a shows the experimental data for pure component isotherms of Bz and Cy in DAT-MOF-1; the continuous solid lines are Langmuir–Freundlich fits (the fit parameters being specified in Table S2, ESI†). For fitting purposes, the sorption branches of the isotherms were solely considered. Fig. 4b shows IAST calculations of Bz uptake capacity for equimolar Bz/Cy mixtures in DAT-MOF-1. Notably, for pressures exceeding about 1 kPa, the adsorbed phase contains predominantly Bz. Fig. 4c presents IAST calculations for adsorption selectivity, $S_{ads}$, for equimolar Bz/Cy mixtures with values in excess of about 200, suggesting the viability of the present MOF material for vapor phase selective sorption based Bz/Cy separation at 298 K. Transient breakthrough simulations, using the established methodology described in earlier work, confirm that sharp separations are obtained in a fixed bed adsorber; see Fig. 4d. The video animation-illustration (accompanied as ESI†) evidently demonstrates that DAT-MOF-1 has both significantly higher selectivity and uptake for Bz over Cy.

In a nutshell, as a first-of-its kind convergent approach, the triazine core’s $\pi$-electron-deficiency coupled with the mutual attendance of amino moieties for the reported DAT-MOF-1 has been strategically exploited for the achievement of selective benzene sorption over its aliphatic analogue cyclohexane. Further investigations to consolidate its practical applications in terms of realistic industrial separation scenario are currently underway. This might indeed help to develop functional porous materials by virtue of their tunable functionalities; immensely important for exhibiting industrially crucial hydrocarbon separation features.

B.M. is thankful to CSIR for research fellowship, while IISER Pune is acknowledged for the same from S.M., A.V.D. and S.S.; DST (Project No. GAP/DST/CHE-12-0083) and DST-FIST (SR/FST/CSII-023/2012) are acknowledged for generous financial support.
