(Received 21 November 2014; published 2 February 2015)

We set up the construction of generic $(d + 2)$ -dimensional metrics corresponding to $(d + 1)$ -dimensional fluids, representing holographically the hydrodynamic regimes of the putative dual theories. We give general seed equilibrium metrics appropriate to generic bulk stress energy tensors and discuss the implications of conformal rescalings of the hypersurface on which the fluid is defined. We then show how to obtain the corresponding hydrodynamic metrics using a relativistic gradient expansion and discuss the integrability conditions of the resulting equations. The stress energy tensors of the resulting fluids, both at and away from equilibrium, satisfy a quadratic constraint. We interpret this constraint in terms of two possible equations of state for the fluid and show that only one of the two equations is physical. We illustrate our discussions with the example of the cutoff anti-de Sitter fluid, for which we find the precise interpretation in terms of deformations of the UV conformal field theory. Finally we discuss the relation between the modern fluid/gravity approach taken in this paper and the earlier membrane paradigm.

I. INTRODUCTION

The holographic principle proposes an equivalence between $(d + 2)$ -dimensional gravitational theories and $(d + 1)$ -dimensional quantum field theories. A concrete realization of holography in which the dictionary between bulk and boundary data has been extensively developed is the case of asymptotically locally anti-de Sitter spacetimes (AdS) corresponding to conformal field theories (CFT). However, if holography is the correct paradigm, holographic descriptions should exist for more general gravitational theories with different asymptotics. Holography has in recent times been pushed beyond AdS asymptotics, particularly to nonrelativistic dualities such as Lifshitz and Schrödinger, but constructing a holographic duality for even asymptotically flat spacetimes has been a long-standing challenge.

A generic feature of any quantum field theory is the existence of a hydrodynamic description capturing the long-wavelength behavior of the microscopic degrees of freedom near to thermal equilibrium. If holography is correct, such regimes have to be reproduced within the context of the holographic duality. The fluid/gravity correspondence [1] exactly realizes this scenario: nearby gravitational solutions describing the hydrodynamic regime have been explicitly constructed for AdS black-brane solutions, which correspond to a conformal fluid at thermal equilibrium. This framework was later extended to classes of nonconformal fluids; see for example [2,3]. The authors

of [4] review the many other extensions of the fluid/gravity relation.

An extension of fluid/gravity duality to vacuum Einstein gravity has also been developed over the past few years. In [5–7], the incompressible Navier-Stokes equations in $(d + 1)$ dimensions were shown to be dual to a $(d + 2)$ -dimensional Ricci-flat metric. This holographic duality for Ricci-flat spacetime has attracted much interest and the correspondence has been extended in several directions. A systematic construction of the metric to all orders in the hydrodynamic expansion was provided in [7]; this determines the corresponding specific corrections to the incompressible Navier-Stokes equations. Subsequently in [8,9] the fluid/gravity relation was reformulated in a manifestly relativistic expansion. The thermal state corresponds to the Rindler spacetime and near equilibrium solutions represent the hydrodynamic behavior of a dual fluid living on a finite cutoff timelike hypersurface Σ_c . In [10] relations among the second order transport coefficients have been derived and the authors of [11–13] studied higher derivative corrections. Extensions to spherical horizon topologies and to de Sitter have been studied in [14–17] while charged fluids were explored in [18–20]. The role of Petrov conditions has been explored in [15,21–24] and solution generating symmetries were investigated in [25]. Other related works include [26–30].

In this paper we give a general prescription for constructing hydrodynamic solutions associated with a $(d + 1)$ -dimensional timelike flat hypersurface Σ_c inside a $(d + 2)$ -dimensional bulk spacetime, which has a horizon and is supported by a generic bulk stress tensor. Note that this hypersurface does not necessarily need to be chosen to

*N.PinzaniFokeeva@uva.nl

†M.M.Taylor@soton.ac.uk

be near the horizon or near the (conformal) boundary of the space-time. We begin in Sec. II by setting up an appropriate form for a bulk metric dual to an equilibrium fluid and its relation to the Bondi-Sachs form [31,32] as well as the metric ansatz used in holographic numerical simulations such as [33].

By construction, when the hypersurface Σ_c is flat, the induced Brown-York stress energy tensor on this hypersurface takes a fluid form, and one can read off the defining properties of the putative dual fluid. We highlight the fact that, when the hypersurface is only conformally flat, as is indeed the case for AdS/CFT, the holographic stress tensor cannot be the Brown-York stress energy tensor but rather should be conformal to the Brown-York stress energy tensor. We also emphasize the implications of the fact that fixing a Dirichlet Minkowski condition on Σ_c generically leads to noncanonical normalizations of Killing vectors both at asymptotic infinity and at the horizon.

As noted in [8,9], the fluid stress energy tensor satisfies a quadratic constraint, which acts as an equation of state. This implies that, for any given data for the bulk stress energy tensor on Σ_c , there are two distinct bulk solutions. For vanishing bulk stress energy tensor these correspond to the Rindler fluid and the Taub fluid, respectively [8,9]. The Taub fluid has strictly negative energy density and temperature and is hence unphysical. In Sec. III we consider various examples of bulk stress energy tensors, including cosmological constant and gauge fields, and we discuss the interpretations of the positive and negative signs in the equation of state. Only one sign in the equation of state gives rise to a physical fluid; the opposite sign is always associated with a negative temperature and is therefore not physical.

Using our examples, we observe that the existence of a flat timelike hypersurface is (as one would expect) highly nontrivial: in the absence of negative bulk curvature this requirement forces us into scaling regions of black holes with spherical horizon topologies. We also note that in the presence of generic matter the Einstein equations no longer form a nested hierarchy of decoupled equations, as they do in the vacuum and cosmological constant cases; see [31,32] and [33]. Since the equations do not decouple, even equilibrium (stationary) solutions are hard to find.

In Sec. IV we begin a preliminary investigation of the relation between the fluid stress energy tensor and the renormalized holographic stress energy tensor, the latter being defined in cases for which the holography duality is under control, e.g. asymptotically AdS or Lifshitz spacetimes. We use this perspective to understand why the fluid stress energy tensor for conformally flat hypersurfaces must be defined in terms of the conformally rescaled Brown-York stress energy tensor.

In Sec. V we provide a general setup for hydrodynamics by promoting the defining parameters of the equilibrium bulk solutions to be position dependent. Working in a

relativistic gradient expansion, we work out the hydrodynamic equations of motion. We show that the conservation of the dual fluid is associated with the integrability of the bulk equations and we derive a general expression for the first order dissipative corrections to the fluid stress energy tensor.

As an example of our formalism we revisit the case of cutoff AdS. We compute the first order hydrodynamic metric corresponding to a Dirichlet condition on the hypersurface Σ_c . As this hypersurface is taken towards the conformal boundary we recover the results of [1]. For a generic choice of Σ_c , we work out the asymptotic expansion of the metric in the neighborhood of the conformal boundary. This metric remains asymptotically locally AdS but the background metric for the dual CFT is no longer conformally flat. We give the precise form for this background metric, up to first order in derivatives, thereby identifying the precise deformation of the dual CFT captured by the Dirichlet condition in the bulk. Earlier discussions of the mixed nature of the boundary condition at infinity can be found in [5,34,35]; see also the related work [36]. Discussions of the hydrodynamic behavior on a finite cutoff hypersurface Σ_c include [37,38]; see also [39,40].

The fluid/gravity duality is not the first time in which the physics of fluids has been linked to that of gravity. The membrane paradigm was introduced in [41–43] and the authors postulate that any black hole horizon can be thought of as a membrane exhibiting fluidlike behavior. In particular it was shown that certain components of Einstein equations could be recast in the form of dissipative nonrelativistic Navier-Stokes equations. This fluid however has a negative bulk viscosity, a signal that this membrane fluid is unphysical, and that the membrane paradigm itself should perhaps only be considered as a formal (if convenient) treatment of horizon dynamics.

A natural question is what is the relation between the membrane paradigm and modern fluid/gravity approaches. It was already noted in [44] that in fluid/gravity duality the dynamics of the entire spacetime is encoded holographically by the fluid associated with the boundary of the spacetime, while the membrane fluid is encoded on the horizon; see also the related works [45–48]. An extension of the membrane paradigm to hypersurfaces in the interior of the spacetime has been studied in [49], and recent works attempting to find connections between the membrane paradigm and fluid/gravity by studying hydrodynamic behavior on a finite cutoff hypersurface Σ_c include [37,38], as well as [39,40].

In Sec. VI we discuss the relation between the fluid/gravity approach and the membrane paradigm, by developing the work of [50]. The latter generalized the Damour equations to the case of general hypersurfaces foliating the bulk spacetime, with the hypersurfaces not necessarily being null and not being assumed to be close to the horizon. In particular, [50] constructed a generalized

Damour-Navier-Stokes equation on codimension 1 time-like hypersurfaces. We extend the work of [50] to other components of the Einstein equations and then use this setup to compare the membrane approach with the fluid/gravity construction. We highlight the different identifications of both fluid parameters and the associated transport coefficients in the two approaches. In Sec. VII we conclude, while the appendixes contain detailed derivations of certain results used in the main text.

II. GENERIC FLUIDS IN EINSTEIN GRAVITY

A. The general seed metric ansatz

We are interested in studying the hydrodynamics of fluids associated with a $(d+1)$ -dimensional timelike flat hypersurface Σ_c foliating a $(d+2)$ -dimensional bulk spacetime. We begin by considering a generic static solution; having constructed static seed solutions one can always boost them to obtain stationary solutions corresponding to fluids with nonzero velocity. A convenient metric ansatz in Eddington-Finkelstein-type coordinates is of the form

$$ds^2 = 2dt dr - f(r)dt^2 + g(r)dx^i dx_i, \quad (1)$$

with $i = 1, \dots, d$. On hypersurfaces Σ_c of constant $r = r_c$ the induced metric is therefore

$$ds^2|_{\Sigma_c} = \gamma_{ab}dx^a dx^b = -f(r_c)dt^2 + g(r_c)dx_i dx^i, \quad (2)$$

where $x^a = (t, x^i)$. We assume that the hypersurface under consideration has a nondegenerate metric, i.e. $f(r_c)$, $g(r_c) \neq 0$, and that there is a horizon at $r = r_H \neq r_c$ where $f(r_H) = 0$. Each hypersurface is a worldline of observers with constant acceleration

$$a = \frac{1}{2} \frac{f'}{\sqrt{f}}, \quad (3)$$

where the prime denotes a radial derivative. The temperature associated with the horizon is

$$T = \frac{1}{4\pi} f'(r_H). \quad (4)$$

After rescaling the coordinates $t \rightarrow \bar{t} = \sqrt{f(r_c)}t$ and $x^i \rightarrow \bar{x}^i = \sqrt{g(r_c)}x^i$ the induced metric on Σ_c can always be written in a manifestly flat form; i.e. the metric is

$$ds^2 = \frac{2d\bar{t}dr}{\sqrt{f(r_c)}} - \frac{f(r)}{f(r_c)}d\bar{t}^2 + \frac{g(r)}{g(r_c)}d\bar{x}_i d\bar{x}^i. \quad (5)$$

Boosting this metric results in

$$ds^2 = -\frac{2}{\sqrt{f(r_c)}}u_a d\bar{x}^a dr + \frac{g(r)}{g(r_c)}d\bar{x}_a d\bar{x}^a + \left(\frac{g(r)}{g(r_c)} - \frac{f(r)}{f(r_c)}\right)(u_a d\bar{x}^a)^2, \quad (6)$$

where the velocity is

$$u^a = \gamma(1, v^i); \quad \gamma = (1 - v^i v_i)^{-1/2}, \quad (7)$$

as usual. The boost manifestly preserves the induced metric on Σ_c . Defining

$$G(r) \equiv \frac{g(r)}{g(r_c)}; \quad F(r) \equiv \frac{f(r)}{f(r_c)}; \quad \lambda \equiv \sqrt{f(r_c)}, \quad (8)$$

such that $G(r_c) = F(r_c) = 1$, the metric can be written as

$$ds^2 = -\frac{2}{\lambda}u_a d\bar{x}^a dr + G(r)d\bar{x}_a d\bar{x}^a + (G(r) - F(r))(u_a d\bar{x}^a)^2. \quad (9)$$

The latter is a generic form for the equilibrium metric; in most of what follows we will work with the metric in this form and we will drop the barred notation for the rescaled coordinates. This is the most general seed equilibrium metric, with the corresponding fluid parameters [see below, (34) and (35)] being $(u_a, G'(r_c), F'(r_c))$ where again the primes denote radial derivatives. Depending on the bulk stress energy tensor and matter present, the fluid may have other parameters. For example, if there is a bulk gauge field then the ansatz for the gauge field consistent with stationarity would be

$$\underline{A} = (\mu(r) + (r - r_c)\rho(r))u_a dx^a. \quad (10)$$

Then one would regard $\mu(r_c)$ as a boundary condition, characterizing the chemical potential in the field theory, and $\rho(r_c)$ as characterizing the charge density in the fluid. Not all of the fluid parameters are independent, since they are related by the Hamiltonian constraint, equivalent to the equation of state for the fluid, as well as conservation equations. For example, for a cosmological constant stress energy tensor, the equation of state implies that only one out of $F'(r_c)$ and $G'(r_c)$ is independent.

The original metric ansatz (1) is analogous to that used in [33] and subsequent works, although in these papers $g(r)$ was rewritten as the square of a function, i.e. $g(r) = \Sigma(r)^2$. By rescaling the radial coordinate one can rewrite the metric in a static Bondi-Sachs [31,32] parametrization:

$$ds^2 = 2e^{2\beta(r_b)}dt dr_b - e^{2\phi(r_b)+4\beta(r_b)}dt^2 + r_b^2 dx^i dx_i, \quad (11)$$

where r_b is the new radial coordinate and $f(r) \equiv e^{2\phi(r_b)+4\beta(r_b)}$ with $e^{2\beta(r_b)} = 2\sqrt{g}(\partial_r g)^{-1}$. This form of the

metric is particularly convenient for solving the vacuum Einstein equations, as they form a nested hierarchy with the equation for β solvable first, and then ϕ may be found using the solution for β . In [33] the same nested hierarchy was found in the case of pure cosmological constant: again $g(r)$ could first be determined, with $f(r)$ then determined using the solution for $g(r)$. We will recover the same structure below but for a generic bulk stress energy tensor one cannot in general analytically integrate the equation for $g(r)$ even in static equilibrium situations.

Let us return for a moment to the original coordinates in (1). Clearly the induced metric on Σ_c given in (2) is conformal to a flat metric in which the effective speed of light is given by

$$c_l^2 = \frac{f(r_c)}{g(r_c)}. \quad (12)$$

Near the horizon, $f(r_c)$ is small and therefore the effective speed of light approaches zero. If one works with the original coordinates, rather than the rescaled coordinates, then the boost should preserve the induced metric on Σ_c . This implies that the boost must use c_l as the effective speed of light, resulting in

$$ds^2 = -2\frac{U_a}{c_l}dx^a dr + g(r)(dx^i dx_i - c_l^2 dt^2) + (U_a dx^a)^2 \left(g(r) - \frac{f(r)}{c_l^2} \right) \quad (13)$$

with

$$U_a = \gamma_l \left(c_l, \frac{v_i}{c_l} \right); \quad \gamma_l^2 = (1 - c_l^{-2} v_i v^i)^{-1}. \quad (14)$$

Defining $\hat{t} = c_l t$ this boosted metric becomes

$$ds^2 = -2\frac{\hat{U}_a}{c_l}dx^a dr + g(r)(dx^i dx_i - d\hat{t}^2) + (\hat{U}_a dx^a)^2 \left(g(r) - \frac{f(r)}{c_l^2} \right) \quad (15)$$

with

$$\hat{U}_a = \hat{\gamma}_l(1, \hat{v}_i); \quad \hat{\gamma}_l^2 = (1 - \hat{v}^i \hat{v}_i)^{-1}, \quad (16)$$

and $\hat{v}_i = dx^i/d\hat{t}$.

In equilibrium the three forms of the metric (9), (13) and (15) differ from one another by trivial rescalings of the coordinates. Once one goes beyond equilibrium into the hydrodynamic regime, however, the three forms of the metric are no longer equivalent. The reason is that the metric functions $f(r)$ and $g(r)$ depend on the thermodynamic quantities: the temperature, charge etc. In the

hydrodynamic regime the latter are promoted to be spatially dependent, and therefore both the conformal factor of Σ_c in (13) and the effective speed of the light c_l on Σ_c become spatially dependent. Using the coordinates of (15), the effective speed of light on the hypersurface does not vary along Σ_c but the conformal factor of the induced metric is still (in general) becoming spatially dependent as one extends the solution into the hydrodynamic regime. By working with the coordinates (9) one ensures that the induced metric on Σ_c remains flat. In other words, this choice of coordinates is appropriate if one wants to impose a fixed Dirichlet boundary condition on Σ_c .

It is useful to make one further rewriting of (9) to obtain

$$ds^2 = -\frac{2}{\lambda} u_a dx^a dr + G(r) h_{ab} dx^a dx^b - F(r) u_a u_b dx^a dx^b, \quad (17)$$

where $h_{ab} = \eta_{ab} + u_a u_b$, with the inverse metric being

$$g^{(0)rr} = \lambda^2 F; \quad g^{(0)ra} = \lambda u^a; \quad g^{(0)ab} = \frac{h^{ab}}{G}. \quad (18)$$

The Ricci tensor is then¹

$$\begin{aligned} R_{rr}^{(0)} &= \frac{dG'^2}{4G^2} - \frac{dG''}{2G}, \\ \lambda^{-1} R_{ra}^{(0)} &= u_a \left(\frac{1}{2} F'' + \frac{dG' F'}{4G} \right), \\ \lambda^{-2} R_{ab}^{(0)} &= u_a u_b \left(\frac{1}{2} F F'' + \frac{dG' F F'}{4G} \right) \\ &\quad + h_{ab} \left(\frac{(2-d) G'^2 F}{4G} - \frac{1}{2} F' G' - \frac{1}{2} F G'' \right), \end{aligned} \quad (19)$$

where in anticipation of extending to the hydrodynamic regime the superscript denotes that we are working to zeroth order in x^a derivatives.

We assume that the metric satisfies Einstein's equations with a given stress energy tensor; i.e. the Einstein tensor satisfies

$$G_{\mu\nu} = T_{\mu\nu}. \quad (20)$$

Throughout this paper we will use $\mathcal{T}$ to denote the bulk stress energy tensor and reserve T to denote the stress energy tensor associated with the fluid on Σ_c . Einstein's equations then read

¹Our convention for the Riemann tensor is $R_{\rho\nu\sigma}^\mu = \partial_\nu \Gamma_{\rho\sigma}^\mu + \Gamma_{\lambda\nu}^\mu \Gamma_{\rho\sigma}^\lambda - (\nu \leftrightarrow \sigma)$. Details of the computation of the curvature at leading and subleading order may be found in the Appendix.

$$\begin{aligned}
G'' &= \frac{1}{2} \frac{G'^2}{G} - \frac{2G}{d} T_{rr}^{(0)}, \\
F'G' &= -\frac{1}{2}(d-1) \frac{FG'^2}{G} + \frac{4GF}{d} T_{rr}^{(0)} + \frac{4G}{d\lambda} T_{ra}^{(0)} u^a, \\
F'' &= \frac{2}{d\lambda^2 G} T_{ab}^{(0)} h^{ab} + \frac{1}{4} d(d-1) \frac{FG'^2}{G^2} + \\
&\quad - \frac{2}{d}(d-1) F T_{rr}^{(0)} - \frac{4(d-1)}{d\lambda} T_{ra}^{(0)} u^a, \tag{21}
\end{aligned}$$

where again the superscript denotes working to zeroth order in x^a derivatives. These equations are the (rr) , (ra) on u^a and (ab) on h^{ab} projection of the Einstein equations, respectively. Clearly there are constraints on the bulk stress energy tensor such that the metric takes the required stationary form and these are reflected in the final independent Einstein equation, which implies

$$T_{ar}^{(0)} F\lambda + T_{ab}^{(0)} u^b = 0. \tag{22}$$

One can understand this latter constraint as follows. Taking the static limit of the metric (9), a bulk stress energy tensor compatible with the symmetries must be characterized by three scalar functions as

$$\begin{aligned}
T_{\mu\nu}^{(0)} dx^\mu dx^\nu &= T^{(0)r} dr^2 + T^{(0)t} dt \left(dt - \frac{2}{\lambda F} dr \right) + T^{(0)i} dx^i dx_i; \\
&= \left(T^{(0)r} - \frac{T^{(0)t}}{\lambda^2 F^2} \right) dr^2 + T^{(0)t} dt_s^2 + T^{(0)i} dx^i dx_i, \tag{23}
\end{aligned}$$

where t_s is the Schwarzschild time, such that $dt_s = dt - dr/\lambda F$. Conservation of the bulk stress energy tensor implies that only two out of these three functions are independent. Under a boost the form of the stress energy tensor becomes

$$\begin{aligned}
T_{\mu\nu}^{(0)} dx^\mu dx^\nu &= T^{(0)r} dr^2 + \frac{2}{\lambda F} T^{(0)t} dr du^a \\
&\quad + T^{(0)t} (u_a dx^a)^2 + T^{(0)i} h_{ab} dx^a dx^b. \tag{24}
\end{aligned}$$

Thus we recover the constraint (22) together with the fact that

$$T_{ab}^{(0)} = T^{(0)i} h_{ab} + T^{(0)t} u_a u_b; \tag{25}$$

i.e. there are only two independent (ab) Einstein equations, that projected onto h_{ab} and that projected onto $u^a u^b$.

It is useful to write down the combination of the Einstein equations which gives the Hamiltonian constraint in a radial slicing of the spacetime as

$$K^2 - K_{ab} K^{ab} = {}^{d+1}R + 2G_{\mu\nu} n^\mu n^\nu, \tag{26}$$

where K_{ab} is the extrinsic curvature on the timelike hypersurfaces Σ_c , $K = K_{ab} \gamma^{ab}$ is its trace, ${}^{d+1}R$ is the Ricci scalar of the timelike hypersurface Σ_c and n^μ is the unit normal vector to the hypersurfaces Σ_c . The latter is given by

$$\vec{n} = \lambda \partial_r + u^a \partial_a; \quad \underline{n} = \frac{1}{\lambda} dr. \tag{27}$$

Since we are interested in the case in which the hypersurface Σ_c is intrinsically flat this constraint reduces to

$$K^2 - K^{ab} K_{ab} = 2\lambda^{-2} T^{rr}, \tag{28}$$

where we use $F(r_c) = 1$. It is straightforward to show that this Hamiltonian constraint can be rewritten as a constraint equation for the Brown-York stress energy tensor [51] defined on Σ_c

$$T_{ab} = 2(K\gamma_{ab} - K_{ab}) \tag{29}$$

as

$$dT_{ab} T^{ab} - T^2 = -8d\lambda^{-2} T^{rr}. \tag{30}$$

This constraint effectively defines an equation of state for the fluid. Since the equation is quadratic, one can always find two possible solutions for given data for T^{rr} on Σ_c . In the following section we will interpret the two distinct solutions for generic bulk stress energy tensors.

The (ar) components of the Einstein equations can be expressed as the momentum constraint

$$D_c K_a^c - D_a K = T_{a\sigma} n^\sigma, \tag{31}$$

where D_a is the covariant derivative in the induced geometry γ_{ab} . Requiring that the Brown-York stress energy tensor is conserved on Σ_c implies the constraint

$$T_{ar} \lambda + T_{ab} u^b = 0, \tag{32}$$

which is indeed satisfied in our equilibrium configurations due to (22); recall that $F(r_c) = 1$ by construction.

The Brown-York stress energy tensor on the generic timelike hypersurface Σ_c can be explicitly expressed in the perfect fluid form as

$$T_{ab} = p h_{ab} + \rho u_a u_b \tag{33}$$

where p is the pressure and ρ is the energy density, given by

$$p = \lambda((d-1)G'(r_c) + F'(r_c)), \tag{34}$$

$$\rho = -d\lambda G'(r_c); \tag{35}$$

i.e. the values of the gradients of the metric functions, together with λ , characterize the pressure and energy density of the fluid. There is an apparent redundancy in these expressions, as the two thermodynamic quantities are expressed in terms of three metric parameters. However, recall that λ characterizes the rescaling of the time coordinate on the hypersurface Σ_c , (8). By choosing the time coordinate to be adapted to this hypersurface one can always take $\lambda = 1$ but then the time Killing vector at asymptotic infinity will not have its usual normalization. Therefore λ measures the relative normalization of the Killing vector.

Now let us move to the interpretation of the fluid on Σ_c and let the stress energy tensor of the fluid be denoted T_{ab}^F . *A priori*, this cannot be assumed to be precisely the Brown-York stress energy tensor as any linear combination of the latter with covariant tensors built from the intrinsic metric γ_{ab} on the hypersurface Σ_c and its curvature would also be conserved. Given that the induced metric is intrinsically flat, the following stress tensor

$$T_{ab}^F = C_1 T_{ab} + C_2 \eta_{ab} \quad (36)$$

would be conserved for any values of the constants C_1 and C_2 . In the following section we will argue why C_1 should be precisely 1 in a holographic theory, when the induced metric on Σ_c is the Minkowski metric. However, as in previous works [6–8], C_2 remains an ambiguity, which shifts

$$p \rightarrow p + C_2, \quad \rho \rightarrow \rho - C_2 \quad (37)$$

but does not change the combination $(p + \rho)$:

$$(p + \rho) = \lambda(F'(r_c) - G'(r_c)). \quad (38)$$

The latter combination of course appears in the thermodynamic relation

$$(p + \rho) = sT + \dots = \lambda F'(r_H)(G(r_H))^{d/2} + \dots \quad (39)$$

where the ellipses denote additional contributions from charges etc. and we use

$$s = 4\pi(G(r_H))^{d/2}; \quad T = \lambda \frac{F'(r_H)}{4\pi}. \quad (40)$$

Therefore C_2 does not lead to any ambiguity in the thermodynamic relations.

To understand the role of the prefactor C_1 one should consider the effect of a conformal transformation on the hypersurface metric: if one scales $\gamma_{ab} \rightarrow \Omega^2 \gamma_{ab}$, this is equivalent to a rescaling of the coordinates as $x^a \rightarrow \Omega x^a$. Under such a rescaling, it is easy to see that

$$p \rightarrow \Omega^{-2} p; \quad \rho \rightarrow \Omega^{-2} \rho; \quad s \rightarrow \Omega^{-d} s; \quad T \rightarrow \Omega^{-1} T. \quad (41)$$

The implication of these scaling relations is as follows. If the thermodynamic relation is satisfied when the induced metric on Σ_c is Minkowski, with T being the horizon temperature, then the thermodynamic relation is not satisfied for any nontrivial conformal factor Ω unless an appropriate prefactor C_1 is included. For the thermodynamic relation to be satisfied, one needs to relate the fluid stress energy tensor T_{ab}^F to the Brown-York stress energy tensor T_{ab} as

$$T_{ab}^F = \Omega^{1-d} T_{ab} + \dots, \quad (42)$$

where the ellipses denote terms built from the induced metric and, in the general case for which the induced metric is not flat, its curvature. As noted above, this tensor is also conserved, provided that the conformal factor Ω is independent of the coordinates on the hypersurface. This expression closely resembles the expression for the renormalized stress energy tensor in AdS/CFT and indeed we will discuss the relationship between the two tensors later.

Finally let us reconsider the alternative forms of the equilibrium metrics (13) and (15) in the context of this discussion. The background metric for the fluid is the induced metric on Σ_c , namely

$$ds^2 = g(r_c)(dx^i dx^i - c_i^2 dt^2) \equiv \gamma_{ab} dx^a dx^b, \quad (43)$$

which is only conformally flat. With this form of the metric the entropy density and temperature are given by

$$s = 4\pi(g(r_H))^{d/2} \equiv 4\pi(G(r_H))^{d/2}(g(r_c))^{d/2};$$

$$T = \frac{1}{4\pi c_i} f'(r_H) \equiv \frac{1}{4\pi} F'(r_H)(g(r_c))^{1/2}. \quad (44)$$

The Brown-York tensor associated with a hypersurface Σ_c in the metric in (13) is

$$T_{ab} dx^a dx^b = \lambda \left((d-1) \frac{g'(r_c)}{g(r_c)} + \frac{f'(r_c)}{f(r_c)} \right)$$

$$\times g(r_c)(dx^i dx_i - c_i^2 dt^2 + U_a U_b dx^a dx^b)$$

$$- \lambda d \frac{g'(r_c)}{g(r_c)} (U_a U_b dx^a dx^b), \quad (45)$$

which can be rewritten as

$$T_{ab} = p(\gamma_{ab} + g(r_c)U_a U_b) + \rho g(r_c)U_a U_b, \quad (46)$$

where the quantities p and ρ are as given in (34)–(35). However, these are *not* the physical pressure and energy density of the fluid: appropriate conformal factors of $g(r_c)$

must be included in the latter according to the prescription (42) for the thermodynamic relation to be satisfied.

In equilibrium the choice of coordinate system is merely one of computational convenience but away from equilibrium different choices really correspond to distinct boundary conditions on the hypersurface Σ_c . For example, it is only sensible to keep the induced metric on Σ_c fixed as (43) when one extends to the hydrodynamic regime if the conformal factor $g(r_c)$ is independent of the fluid parameters, as well as the speed of light c_l^2 . If the conformal factor depends on the fluid parameters then implicitly the background metric on Σ_c is only flat to leading order in the hydrodynamic expansion. Moreover the fluid stress energy tensor defined in (42) would also only be conserved to leading order in gradients. In practice, as we discuss in the next section, for many bulk stress energy tensors one can immediately integrate the equations of motion to obtain $g(r) = r^2$, which is independent of the fluid parameters.

III. EXAMPLES OF FLUIDS

In this section we consider examples of fluids with various bulk stress energy tensors. In particular, we explore the interpretation of the two solutions for the equation of state (30).

A. Negative cosmological constant

Our first example is the case in which the bulk stress energy tensor is a negative cosmological constant, namely $T_{\mu\nu} = -\Lambda g_{\mu\nu}$. In this case the Hamiltonian constraint (30) can be written in terms of the metric (1) as

$$d\tau'(f' + (d-1)f\tau') + 2\Lambda = 0, \quad (47)$$

where $e^{2\tau(r)} = g(r)$. This gives two possible equations of state for the fluid

$$\rho = -\frac{pd}{(d-1)} \pm \frac{1}{(d-1)} \sqrt{d^2 p^2 + 8d(d-1)\Lambda}, \quad (48)$$

from which we then obtain two possible geometries for two distinct dual fluids. Notice that in the limit $\Lambda \rightarrow 0$ we recover the two already known results, namely the Rindler equation of state $\rho = 0$ (see e.g. [8]) and the Taub geometry² equation of state $\rho = -\frac{2d}{d-1}p$ (see [9]).

The general solution to the (rr) Einstein equation is

$$g(r) = (c_1 r + c_2)^2 \quad \text{with} \quad c_1 \neq 0. \quad (49)$$

Here c_1 and c_2 denote integration constants. The special case $c_1 = 0$ and $g(r)$ constant is not compatible with the

other equations of motion unless $\Lambda = 0$. Let us set $c_1 = \frac{1}{L}$, rescale the r coordinate $\frac{r}{L} = \frac{r}{L} + c_2$ and use the same symbol for the radial coordinate $\bar{r} \rightarrow r$. The remaining Einstein equations provide a solution for $f(r)$ which reads

$$f(r) = -\frac{2}{d(d+1)}\Lambda r^2 + \frac{c_3}{r^{d-1}}. \quad (50)$$

Consider first the case $c_3 \neq 0$. Inserting into (50) the value of the cosmological constant $\Lambda = -\frac{d(d+1)}{2L^2}$ relevant to the maximally symmetric spacetime with negative curvature, the static metric (1) represents a “naked-brane” or a black-brane geometry depending on the sign of c_3 ; i.e. the metric is

$$ds^2 = -\frac{r^2}{L^2} \left(1 + \frac{c_3 L^2}{r^{d+1}}\right) dt^2 + \frac{r^2}{L^2} dx^i dx_i + 2dt dr. \quad (51)$$

Note that in the limit $\Lambda \rightarrow 0$ the Taub geometry with a positive or negative g_{tt} (depending on the sign of c_3) is recovered; the limit is obtained by scaling $x^i/L \rightarrow x^i$ with $L \rightarrow \infty$ and (t, r) finite. The case with $c_3 > 0$ is the well-known unphysical negative mass black brane, with naked singularity at $r = 0$, and we shall not consider it further here. Conversely setting $c_3 L^2 = -r_H^{d+1}$, the resulting geometry is that of a (positive mass) AdS black brane in ingoing Eddington-Finkelstein coordinates:

$$ds^2 = -\frac{r^2}{L^2} h(r) dt^2 + \frac{r^2}{L^2} dx^i dx_i + 2dt dr, \quad (52)$$

$$h(r) = \left(1 - \left(\frac{r_H}{r}\right)^{d+1}\right).$$

The dual fluid living on a generic timelike hypersurface Σ_c of constant r_c satisfies the equation of state (48) with a positive sign. Boosting and then rescaling to bring the metric into the form (9) with

$$G(r) = \frac{r^2}{r_c^2}; \quad F(r) = \frac{r^2 h(r)}{r_c^2 h_c}; \quad \lambda = \frac{r_c}{L} \sqrt{h_c}, \quad (53)$$

its thermodynamic properties can be obtained immediately from (34)–(35):

$$\rho = -\frac{2d}{L} h_c^{1/2}, \quad (54)$$

$$p = \frac{1}{L h_c^{1/2}} (2d h_c + r_c h'(r_c)), \quad (55)$$

where here and in what follows we use the shorthand notation $h_c \equiv h(r_c)$. Notice that in the near horizon limit $r_c \rightarrow r_H$ the pressure and energy density behave as

²The Taub geometry is a vacuum, homogeneous but anisotropic solution of Einstein gravity first found in four bulk spacetime dimensions in [52]. There is a curvature singularity at $r = 0$ which is timelike and naked.

$$\rho \rightarrow \mathcal{O}(r_c - r_H)^{\frac{1}{2}}, \quad (56)$$

$$p \rightarrow \sqrt{(d+1)} \frac{\sqrt{r_H}}{L} \frac{1}{\sqrt{r_c - r_H}} + \mathcal{O}(r_c - r_H)^{\frac{1}{2}} \quad (57)$$

and thus have the same behavior as the corresponding thermodynamic quantities of the Rindler fluid³ (see [8]), provided that the constant k is identified with the surface gravity of the black brane as

$$k = \frac{(d+1)}{2L^2} r_H. \quad (58)$$

The energy density (54) is negative, but as already mentioned one can use the ambiguity in the definition of the Brown-York stress energy tensor (36) in order to shift the energy density to a positive value. Moreover, the thermodynamic relation

$$(\rho + p) = \frac{d+1}{L h_c^{1/2}} \frac{r_H^{d+1}}{r_c^{d+1}} \quad (59)$$

is independent of this ambiguity. The Hawking temperature computed from the metric (9) with the time coordinate rescaled is

$$T_H = \frac{(d+1)}{4\pi r_c L} \frac{r_H}{\sqrt{h_c}}. \quad (60)$$

The entropy density of the horizon, again expressed in terms of the rescaled coordinates, is

$$s = 4\pi \frac{r_H^d}{r_c^d}, \quad (61)$$

and thus the thermodynamic relation (59) is indeed satisfied. The $c_3 \rightarrow 0$ limit gives the AdS vacuum metric expressed in ingoing coordinates

$$ds^2 = -\frac{r^2}{L^2} dt^2 + \frac{r^2}{L^2} dx^i dx^i + 2dt dr, \quad (62)$$

with the energy density and the pressure being

$$\rho = -\frac{2d}{L}, \quad p = \frac{2d}{L}, \quad (63)$$

where again these are evaluated in coordinates in which the induced metric on the hypersurface is Minkowski. These

³After restoring the dimensionful parameter k , the flat space-time metric in Rindler coordinates is written $ds^2 = -(kr)^2 d\hat{t}^2 + dx^i dx^i + dr^2$ and in ingoing Rindler coordinates is $ds^2 = -2kr d\hat{t}^2 + dx^i dx^i + 2dt dr$. It is straightforward to show that the thermodynamic quantities of the dual fluid living on a generic timelike hypersurface Σ_c of constant $r = r_c$ are $p_R = \sqrt{2k} \frac{1}{\sqrt{r_c}}$, $\rho_R = 0$.

values may be viewed as the boundary limit ($r_c \rightarrow \infty$) and the vacuum AdS limit ($r_H \rightarrow 0$) of the thermodynamic quantities found in (54)–(55).

The arbitrariness in the definition of the fluid stress energy tensor (36) can be used to redefine the pressure of the dual fluid in order to obtain a vanishing renormalized ideal stress energy tensor T_{ab}^F for the vacuum, choosing $C_2 = -2d/L$. The combination $(\rho + p) = 0$ is invariant and reflects the fact that the AdS spacetime metric (62) has a trivial horizon geometry and thus one cannot associate to it a nonzero entropy. One could however define an Unruh temperature for the observers on timelike hypersurfaces which is nonvanishing but fixed:

$$T = \frac{1}{2\pi L}. \quad (64)$$

The thermodynamic relation $(p + \rho) = Ts$ is trivially satisfied in this limit since the entropy density s is zero.

Before turning to the other independent solution of the Hamiltonian constraint, we should note the following. Suppose we instead choose the induced metric on Σ_c to be the conformally rescaled metric

$$ds^2 = \frac{r_c^2}{L^2} (-d\tilde{t}^2 + d\tilde{x}^i d\tilde{x}^i), \quad (65)$$

in terms of which coordinates

$$s = 4\pi \frac{r_H^d}{L^d}; \quad T_H = \frac{(d+1)}{4\pi L^2} \frac{r_H}{\sqrt{h_c}}. \quad (66)$$

In order for the thermodynamic relation to be satisfied, then as anticipated we need to use (42) to define the energy density and pressure; they are rescaled by a factor of r_c^{d+1}/L^{d+1} relative to (54) and (55).

The effective temperature clearly diverges as Σ_c approaches the horizon but this divergence evidently arises only from the time coordinate rescaling. In other words, in rescaling time so that the induced metric on Σ_c is flat, the effective energy density, pressure and temperature diverge as the hypersurface approaches the horizon. If one worked instead with the coordinate t the temperature and energy density would remain finite but the induced metric (the background metric for the fluid) would as expected become null in this limit.

Finally let us turn to the interpretation of the equation of state with a negative sign. To understand this it is useful to rewrite the equation of state in the form

$$\left(1 - \frac{1}{d}\right)\rho + p = \pm \sqrt{p^2 - 8 \frac{(d-1)}{d} \lambda^{-2} T^{rr}}, \quad (67)$$

which reduces to the equation given in (48) in the case $T^{rr} = -\lambda^2 \Lambda$. The solution given above solves this equation

with a positive sign. A corresponding solution for the equation of state with a negative sign is obtained by taking

$$\rho \rightarrow -\rho; \quad p \rightarrow -p, \quad (68)$$

whenever $\mathcal{T}^{rr} \neq 0$. (When $\mathcal{T}^{rr} = 0$, i.e. vacuum solutions, the equations of state degenerate. The positive sign above gives $\rho = 0$ while the negative sign gives the Taub equation of state.) Now the switch in signs in the energy density and pressure can be achieved by switching the direction of the normal to the hypersurfaces, i.e.

$$n^\mu \rightarrow -n^\mu, \quad (69)$$

which corresponds to changing the sign of the extrinsic curvature of the hypersurface. Physically, however, the negative sign solution gives a negative value for $(\rho + p)$ and therefore the thermodynamic relation $(\rho + p) = sT$ could only be satisfied by a negative temperature. Therefore the second equation of state never gives physically meaningful solutions.

B. Positive cosmological constant

We now turn to the case in which the bulk stress energy tensor is a positive cosmological constant. The spacetime metric (1) solving Einstein equations with positive cosmological constant $\Lambda = \frac{d(d+1)}{2l^2}$ corresponding to $c_3 \geq 0$ in (50) is

$$ds^2 = f(r)dt^2 + \frac{r^2}{l^2}dx^i dx^i + 2dtdr, \quad (70)$$

with

$$f(r) = \frac{r^2}{l^2} \left(1 - \left(\frac{r_H}{r} \right)^{d+1} \right). \quad (71)$$

This metric is related to the AdS_{d+2} -black brane (52) through a Wick rotation of the time coordinate t (i.e. going to Euclidean AdS -type coordinates), of the radial coordinate r and of the AdS radius L :

$$t \rightarrow -it; \quad r \rightarrow ir; \quad l^2 \rightarrow -L^2. \quad (72)$$

The induced metric on hypersurfaces of constant r is positive definite and the unit normal vector is now timelike⁴:

⁴The unit normal vector is defined as

$$\underline{n} = \frac{1}{\sqrt{\pm g^{rr}}} dr, \quad (73)$$

with a plus sign if it is spacelike or a minus sign if it is timelike. Moreover, there is always an arbitrariness in the redefinition $n_\mu \rightarrow -n_\mu$ depending on the direction of the vector. As in the previous case we choose the overall sign so that the hypersurface has positive extrinsic curvature.

$$\underline{n} = -\frac{1}{\sqrt{f}} dr. \quad (74)$$

The metric (70) is a de Sitter brane in the so-called inflationary patch; de Sitter is not static so one could not expect the ansatz to produce a spacetime foliated by timelike hypersurfaces. The existence of the analytic continuation to AdS guaranteed that one could describe de Sitter in this ansatz, with the analytic continuations indicated above.

One can write down the Brown-York tensor on the hypersurface, but it cannot be interpreted as a perfect fluid stress energy tensor since the hypersurface is spacelike. By construction it can of course be interpreted as the analytic continuation of such a fluid stress energy tensor. Note that the metric (70) can be written in the more familiar planar dS coordinates after performing the following change of variables

$$dt = dy - \frac{dr^2}{h(r)}, \quad r^2 = \frac{l^4}{\tau^2}, \quad (75)$$

the resulting metric being

$$ds^2 = \frac{l^2}{\tau^2} \left(h(\tau) dy^2 + dx^i dx^i - \frac{d\tau^2}{h(\tau)} \right), \quad (76)$$

with

$$h(\tau) = 1 - \left(\frac{\tau}{\tau_H} \right)^{d+1}. \quad (77)$$

This is the dS_{d+2} -“S brane” metric⁵ in planar coordinates after identifying l with the dS radius and τ being the dS (inflationary) time coordinate.

C. Fluids for which $\mathcal{T}_{rr} = 0$

Certain matter bulk stress energy tensors compatible with the static ansatz (1) will in addition satisfy $\mathcal{T}_{rr} = 0$. The significance is that if $\mathcal{T}_{rr}$ vanishes, then one can immediately integrate the (rr) Einstein equation to obtain

$$g(r) = (c_1 r + c_2)^2. \quad (78)$$

This integrability is, as mentioned earlier, related to the nested hierarchy found in the Bondi-Sachs [31,32] parametrization for vacuum spacetimes; similarly the case of negative cosmological constant also satisfies this property. As discussed above, vanishing c_1 is generically only consistent with the other Einstein equations when the bulk stress energy tensor is zero. Integrating the (ar) Einstein

⁵Referring to this as a brane, while common in the literature, is somewhat of a misnomer since $\tau = \tau_H$ is a coordinate singularity rather than a brane horizon.

equations one obtains the solution for $f(r)$ in terms of the bulk stress tensor component $\mathcal{T}_{tr}$

$$f(r) = \frac{c_3}{(r + c_2/c_1)^{d-1}} + \frac{2}{d}(r + c_2/c_1)^{1-d} \int^r dr' \mathcal{T}_{r't}(r' + c_2/c_1)^d. \quad (79)$$

In the case where $c_1 = 0$ the remaining Einstein equations imply $f'' = 0$. When c_1 is nonzero one can absorb both constants into a redefinition of the origin and scale of the radial coordinate, $(c_1 r + c_2) \rightarrow r$, and hence

$$f(r) = \frac{c_3}{r^{d-1}} + \frac{2}{dr^{d-1}} \int^r dr' \mathcal{T}_{r't}(r')^d. \quad (80)$$

The class of stress energy tensors for which $\mathcal{T}_{rr} = 0$ includes for example gauge fields. Noting that a vector field stress energy tensor is expressed in terms of the field strength $F_{\mu\nu}$ as

$$\mathcal{T}(F)_{\mu\nu} = 2 \left(F_{\mu\rho} F_{\nu}{}^{\rho} - \frac{1}{4} F^{\rho\sigma} F_{\rho\sigma} g_{\mu\nu} \right) + m^2 \left(A_{\mu} A_{\nu} - \frac{1}{2} A^{\rho} A_{\rho} g_{\mu\nu} \right), \quad (81)$$

then the metric ansatz together with the antisymmetry of $F_{\mu\nu}$ forces the (rr) components in the first line to vanish. The second line involves the mass parameter of the vector field and the vector potential A_{μ} ; the (rr) components vanish if $m^2 = 0$ (i.e. it is a gauge field) or $A_r = 0$. However the latter is generically not implied by the symmetries of the equilibrium static solution, which permit a nonzero $F_{tr}(r)$ as the massive vector field equation is

$$\frac{1}{\sqrt{-g}} \partial_{\mu} (\sqrt{-g} F_{\nu}^{\mu}) = m^2 A_{\nu}, \quad (82)$$

and the (r) component of the left-hand side is therefore generically nonzero. The exception is when $m^2 = 0$: then A_r is still nonzero in a gauge which is regular at the horizon i.e.

$$\underline{A} = a(r) \left(dt - \frac{dr}{f(r)} \right) = a(r) dt_s \quad (83)$$

(with t_s again the Schwarzschild time) but A_r does not appear in the stress energy tensor. Note that in the specific case of four spacetime dimensions a constant field strength in the two spatial directions is also consistent with the required symmetries; this case is relevant for discussing gravity duals to magnetohydrodynamics [19,20].

Consider the case in which the bulk stress energy tensor consists of a cosmological constant and a gauge field. The gauge field equation gives

$$F_{tr} = \frac{q}{r^d}, \quad (84)$$

with the conserved charge being proportional to q and the general solution for $f(r)$ hence becomes

$$f(r) = \frac{c_3}{r^{d-1}} - \frac{2}{d(d+1)} \Lambda r^2 + \frac{2q^2}{d(d-1)r^{2(d-1)}}. \quad (85)$$

For negative cosmological constant we therefore recover AdS charged branes, as expected.

For $\Lambda = 0$ the solution with $c_3 > 0$ describes what might be called a charged Taub fluid: the metric is not asymptotically flat and has a naked singularity at $r = 0$. For $c_3 < 0$ $f(r)$ is positive for $0 < r < r_H$ and negative for $r > r_H$ where $f(r_H) = 0$. In the inner region hypersurfaces of constant r are timelike, but there is a naked singularity and the region is bounded by a horizon. In the outer region hypersurfaces of constant r are spacelike, and both t and r are null coordinates as $r \rightarrow \infty$.

One can understand the relationship of the latter solution to the regions inside a Reissner-Nordstrom black hole as follows. Consider four-dimensional black holes (the generalization to $d > 2$ being straightforward). Start from the metric in ingoing coordinates

$$ds^2 = - \left(1 - \frac{2M}{R} + \frac{Q^2}{R^2} \right) dv^2 + 2dv dR + R^2 d\Omega_2^2. \quad (86)$$

Now zoom into the neighborhood of a point on the two-sphere, which without loss of generality can be chosen to be the north pole, by letting $\theta = \epsilon x$ with $\epsilon \ll 1$ i.e.

$$d\theta^2 + \sin^2 \theta d\phi^2 \approx \epsilon^2 (dx^2 + x^2 d\phi^2). \quad (87)$$

In addition scale the radial coordinate such that $r = \epsilon R$ remains finite and the time coordinate such that $t = v/\epsilon$ stays fixed, and also hold fixed

$$2m \equiv 2M\epsilon^3; \quad q \equiv Q\epsilon^2. \quad (88)$$

Under such rescalings one can see immediately using

$$R_{\pm} = M \pm \sqrt{M^2 - Q^2} \quad (89)$$

that the outer horizon at R_+ is pushed to infinity (in the r coordinate) while the inner horizon at R_- remains at a finite value of r . The resulting metric is

$$ds^2 = -\left(\frac{q^2}{r^2} - \frac{2m}{r}\right)dt^2 + 2dt dr + r^2(dx^2 + x^2 d\phi^2), \quad (90)$$

which is the $d = 2$ case of the metric given above. As discussed above this metric covers the region between an outer horizon, an inner horizon and the singularity.

For positive cosmological constant, the solution with $c_3 > 0$ describes a charged solution with a singularity at $r = 0$ and a horizon at a finite value of $r = r_H$, as discussed in the previous section. The hypersurfaces of constant r are only timelike in the region $r < r_H$. The solution with $c_3 \leq 0$ is more interesting: while the behavior of $f(r)$ at very small r and very large r is unchanged, the function can pass through zero more than once in the intermediate region, corresponding to inner and outer horizons.

D. Fluids for which $\mathcal{T}_{rr} \neq 0$

Many common matter Lagrangians induce stress energy tensors which are compatible with the static ansatz (1) but do not satisfy $\mathcal{T}_{rr} = 0$. In such cases the (rr) Einstein equation does not decouple and one cannot in general immediately solve for $g(r)$ (and hence the other defining functions); the Einstein and matter field equations remain coupled.

To illustrate this point it is useful to consider a class of Lagrangians which have recently received considerable attention in the context of AdS/CMT: (neutral) scalars coupled to vector fields, so-called Einstein-Maxwell-dilaton models. If we express the matter action for a single such scalar ϕ coupled to a vector field A_μ as

$$S_m = - \int d^{d+2}x \sqrt{-g} \left(\frac{1}{2} (\partial\phi)^2 + V(\phi) + \frac{1}{4} e^{\alpha\phi} F^2 + \frac{1}{2} e^{\beta\phi} m^2 A^2 \right), \quad (91)$$

with the scalar potential and the parameters (α, β, m^2) defining the model, then the equations of motion are known to admit Lifshitz, hyperscaling violating Lifshitz solutions and other charged dilatonic black holes for various choices of these parameters. The matter stress energy tensor is

$$\begin{aligned} \mathcal{T}_{\mu\nu} = & \frac{1}{2} (\partial_\mu \phi) (\partial_\nu \phi) - \frac{1}{4} (\partial\phi)^2 g_{\mu\nu} - \frac{1}{2} V(\phi) g_{\mu\nu} \\ & + \frac{1}{2} e^{\alpha\phi} \left(F_{\mu\rho} F_{\nu}{}^\rho - \frac{1}{4} F^{\rho\sigma} F_{\rho\sigma} g_{\mu\nu} \right) \\ & + \frac{1}{2} m^2 e^{\beta\phi} \left(A_\mu A_\nu - \frac{1}{2} A^\rho A_\rho g_{\mu\nu} \right), \end{aligned} \quad (92)$$

and the matter field equations are

$$\square\phi = V'(\phi) + \frac{1}{4} \alpha e^{\alpha\phi} F^2 + \frac{1}{2} \beta m^2 e^{\beta\phi} A^2;$$

$$\nabla_\mu (e^{\alpha\phi} F^{\mu\nu}) = 2m^2 e^{\beta\phi} A^\nu, \quad (93)$$

with ∇_μ the covariant derivative. Consistency with the static, spatially homogeneous ansatz requires⁶

$$\phi = \phi(r); \quad \underline{A} = a(r) \left(dt - \frac{dr}{f(r)} \right) \quad (94)$$

but then $\mathcal{T}_{rr} \neq 0$ whenever $\phi(r) \neq 0$ and/or $m^2 a(r) \neq 0$. The metric plus matter is characterized by four functions but the equations of motion are coupled and nonlinear so they cannot be solved analytically in general. For example, in the case of the pure massive vector (no scalar field) an exact solution at zero temperature with Lifshitz scaling symmetry is known (see e.g. [53]), but corresponding finite temperature blackened solutions have only been found numerically (see for example [54–57]). The zero temperature Lifshitz solution can be written in our coordinate system as

$$\begin{aligned} f(r) &= \frac{r^2}{z^2}; & g(r) &= \left(\frac{r}{z} \right)^{2/z}, \\ a(r) &= 2 \frac{\sqrt{z-1}}{z^2} r; & m^2 &= \frac{d^2}{2z^2}. \end{aligned} \quad (95)$$

In this case the (rr) Einstein equation can be integrated to give an analytic solution for the function $g(r)$, but the latter is no longer given by $g(r) \propto r^2$. The usual form of the Lifshitz metric, i.e.

$$ds^2 = \frac{d\rho^2}{\rho^2} + \left(-\frac{d\tau^2}{\rho^{2z}} + \frac{dx^i dx_i}{\rho^2} \right), \quad (96)$$

is obtained by the redefinitions

$$r = z\rho^{-z}; \quad d\tau = \left(dt - \frac{d\rho}{\rho} \right). \quad (97)$$

IV. RENORMALIZED VERSUS FLUID STRESS ENERGY TENSORS

In this section we will explore the relationship between the fluid stress energy tensor which we have defined and the renormalized holographic stress energy tensor [58–60]. We begin with a brief discussion of holographic renormalization for asymptotically locally AdS spacetimes; see [61] for a review. Asymptotically one can always express such spacetimes in Fefferman-Graham coordinates as

⁶A magnetic flux for a gauge field is again possible only in four spacetime dimensions.

$$ds^2 = L^2 \left(\frac{d\rho^2}{\rho^2} + \frac{1}{\rho^2} g_{ab}(\rho, x) dx^a dx^b \right) \quad (98)$$

where the metric g_{ab} admits an expansion

$$g_{ab}(\rho, x) = g_{(0)ab}(\rho, x) + \cdots + g_{(d+1)ab}(\rho, x) \rho^{d+1} + \cdots \quad (99)$$

The ellipses denote terms which are subleading as $\rho \rightarrow 0$; the form of the expansion depends on the details of the bulk stress energy tensor but in the case of pure cosmological constant ($g_{(0)}, g_{(d+1)}$) are the non-normalizable and normalizable modes, respectively.

Using the defining relation of AdS/CFT [62,63], the expectation value of the dual CFT stress energy tensor is defined as

$$\langle T_{ab}^{\text{CFT}} \rangle = - \frac{2}{\sqrt{-g_{(0)}}} \frac{\delta S_{\text{ren}}}{\delta g_{(0)}^{ab}}, \quad (100)$$

where we work in Lorentzian signature and S_{ren} denotes the renormalized bulk action, in which counterterms have been added to remove the volume divergences. Algorithmically one expresses this in terms of the induced metric γ_{ab} on a hypersurface of constant $\rho = \rho_c$ and the subtracted bulk action S_{sub} as

$$\langle T_{ab}^{\text{CFT}} \rangle = - \lim_{\rho_c \rightarrow 0} \left[\frac{L^{d-1}}{\rho_c^{d-1}} \frac{2}{\sqrt{-\gamma}} \frac{\delta S_{\text{sub}}}{\delta \gamma^{ab}} \right], \quad (101)$$

where the renormalized action is defined as

$$S_{\text{ren}} = \lim_{\rho_c \rightarrow 0} S_{\text{sub}}, \quad (102)$$

with the subtracted action being the bare regulated action plus counterterms which remove volume divergent terms. In the specific case of pure cosmological constant the dual stress energy tensor can be expressed as

$$\langle T_{ab}^{\text{CFT}} \rangle = \lim_{\rho_c \rightarrow 0} \left[\left(\frac{L}{\rho_c} \right)^{d-1} T_{ab}^\gamma \right] = \frac{(d+1)}{L} g_{(d+1)ab} + \cdots, \quad (103)$$

where following [60] (and setting $16\pi G_N = 1$)

$$\begin{aligned} T_{ab}^\gamma &= T_{ab}^{\text{BY}} + T_{ab}^{\text{ct}}, \\ T_{ab}^{\text{BY}} &= 2(K\gamma_{ab} - K_{ab}), \\ T_{ab}^{\text{ct}} &= -\frac{2d}{L} \gamma_{ab} + \cdots, \end{aligned} \quad (104)$$

T_{ab}^{BY} being the Brown-York tensor and the ellipses in the last expression denote contributions due to additional counterterms which vanish when the metric γ is flat.

Restricting to this case, in which the corresponding boundary metric $g_{(0)}$ is flat, the renormalized CFT stress energy tensor is

$$\langle T_{ab}^{\text{CFT}} \rangle = \frac{(d+1)}{L} g_{(d+1)ab}. \quad (105)$$

One can trivially rewrite (103) as

$$\langle T_{ab}^{\text{CFT}} \rangle = \lim_{\Omega \rightarrow \infty} [\Omega^{d-1} (T_{ab}^{\text{BY}} + C_2 \gamma_{ab} + \cdots)] \quad (106)$$

where the induced metric on the hypersurface of constant radius is $\Omega^2 \gamma_{ab}$ and $C_2 = -2d/L$. As anticipated, this is very closely related to the expression used for the fluid stress energy tensor but the CFT stress energy tensor is defined using different hypersurfaces. Starting from the generic fluid metric in ingoing coordinates (9) one can define Schwarzschild coordinates x_s^a such that

$$dx^a = dx_s^a + \frac{u^a dr}{\lambda F(r)}, \quad (107)$$

so that

$$\begin{aligned} ds^2 &= \frac{dr^2}{\lambda^2 F(r)} + G(r) \eta_{ab} dx_s^a dx_s^b \\ &+ (G(r) - F(r)) u_a u_b dx_s^a dx_s^b. \end{aligned} \quad (108)$$

By defining

$$L^2 \frac{d\rho^2}{\rho^2} = \frac{dr^2}{\lambda^2 F(r)}, \quad (109)$$

the metric can be brought into Fefferman-Graham form.

For example, in the AdS black brane (52), by performing the following change of radial coordinates

$$r = \frac{L^2}{\rho} \left(1 + \frac{1}{4} \left(\frac{r_H \rho}{L^2} \right)^{d+1} \right)^{\frac{2}{d+1}}, \quad (110)$$

with inverse transformation

$$\rho = \frac{L^2}{r} \left(\frac{2}{1 + \sqrt{h(r)}} \right)^{\frac{2}{d+1}}, \quad (111)$$

the black-brane metric can be written uniquely in the Fefferman-Graham form requiring the boundary to be at $\rho = 0$ and the Dirichlet condition for the representative of the conformal structure at the boundary $g_{(0)ab} = \eta_{ab}$. The transformed metric is

$$\begin{aligned}
ds^2 &= \frac{L^2}{\rho^2} d\rho^2 + \frac{L^2}{\rho^2} g_{\text{fg}}(\rho) \eta_{ab} dx_s^a dx_s^b \\
&\quad + \frac{L^2}{\rho^2} (g_{\text{fg}}(\rho) - f_{\text{fg}}(\rho)) (u_a dx_s^a)^2, \\
f_{\text{fg}}(\rho) &= \left(1 + \frac{1}{4} \left(\frac{r_H \rho}{L^2}\right)^{d+1}\right)^{\frac{2(1-d)}{(d+1)}} \left(1 - \frac{1}{4} \left(\frac{r_H \rho}{L^2}\right)^{d+1}\right)^2, \\
g_{\text{fg}}(\rho) &= \left(1 + \frac{1}{4} \left(\frac{r_H \rho}{L^2}\right)^{d+1}\right)^{\frac{4}{d+1}}. \tag{112}
\end{aligned}$$

Notice that the coordinate transformation is singular at the horizon $\rho_H = 2^{\frac{2}{d+1}} L^2 / r_H$. A hypersurface of constant r_c is mapped to a radial hypersurface $\rho(r_c)$. The coordinates are chosen such that the induced metric on a radial hypersurface as $\rho \rightarrow 0$ approaches $\eta_{ab} L^2 / \rho^2$.

Expanding the metric (112) around $\rho = 0$ one can extract the holographic CFT stress energy tensor using (105), which is indeed that of a conformal ideal fluid in $(d+1)$ spacetime dimensions:

$$\langle T_{ab}^{\text{CFT}} \rangle = \frac{(4\pi)^{d+1} L^d}{(d+1)^{d+1}} T^{d+1} (h_{ab} + du_a u_b), \tag{113}$$

where $h_{ab} = \eta_{ab} + u_a u_b$. The energy density ρ_e , the pressure p and the temperature T of the dual fluid are

$$\rho_e = \frac{d}{L} \left(\frac{r_H}{L}\right)^{d+1}, \quad p = \frac{1}{L} \left(\frac{r_H}{L}\right)^{d+1}, \quad T = \frac{(d+1)r_H}{4\pi L^2}, \tag{114}$$

with the temperature being the Hawking temperature.

A. Cutoff stress energy tensor

To compare with the discussion in previous sections we now define the stress energy tensor of a dual fluid living on a generic timelike hypersurface Σ_c by taking the expression (103) on a finite radial coordinate ρ_c without taking the limit towards the boundary. In other words, one defines

$$\langle T_{ab}^F \rangle_{\Sigma_c} = \left[\left(\frac{L}{\rho(r_c)} \right)^{d-1} T_{ab}^\gamma \right]_{\Sigma_c}. \tag{115}$$

Since the induced metric on this hypersurface is no longer conformally flat, one needs to rescale the x_s^a coordinates as in the previous section. The stress energy tensor takes the form of an ideal fluid with energy density ρ^F and pressure p^F :

$$\begin{aligned}
\rho^F &= \frac{d}{L} \left(\frac{r_H}{L}\right)^{d+1} \left(1 + \frac{A}{4}\right)^{-1}, \\
p^F &= \frac{1}{L} \left(\frac{r_H}{L}\right)^{d+1} \frac{(1 + \frac{dA}{4})}{(1 - \frac{A^2}{16})}, \tag{116}
\end{aligned}$$

where $A = (\rho_c r_H / L^2)^{d+1}$. In the limit $r_c \rightarrow \infty$ ($A \rightarrow 0$) one recovers the values given above (114) and the stress energy tensor is traceless on the boundary as it should be. Using the relationship (111) between r and ρ coordinates,⁷ (116) can be immediately rewritten as

$$\begin{aligned}
\rho^F &= \frac{2d}{L} \left(\frac{L}{\rho(r_c)} \right)^{d+1} (1 - h_c^{1/2}), \\
p^F &= \frac{1}{L} \left(\frac{L}{\rho(r_c)} \right)^{d+1} \left(2d(h_c^{1/2} - 1) + \frac{r_c h'(r_c)}{h_c^{1/2}} \right), \tag{117}
\end{aligned}$$

where

$$h_c = \left(1 - \frac{r_H^{d+1}}{r_c^{d+1}}\right); \tag{118}$$

which agree with (54) and (55) after taking into account the inclusion of the counterterm and the conformal factor (in Fefferman-Graham coordinates) which gives

$$\rho^F = \left(\frac{L}{\rho(r_c)} \right)^{d+1} \left(\rho + \frac{2d}{L} \right), \tag{119}$$

$$p^F = \left(\frac{L}{\rho(r_c)} \right)^{d+1} \left(p - \frac{2d}{L} \right). \tag{120}$$

The usual conformal fluid pressure and energy density (114) can be now obtained after pushing the cutoff towards the boundary $r_c \rightarrow \infty$.

The agreement between the expressions follows from the form of the coordinate transformations (107) and (109): restricted to a surface of constant r the ingoing and Schwarzschild coordinates coincide. When one extends the solutions into the hydrodynamic regime, however, the corresponding coordinate transformations will be of the form

$$\begin{aligned}
dx^a - u^a(x) \frac{dr}{\lambda(x)F(r,x)} + \dots &= dx_s^a; \\
L \frac{d\rho}{\rho} &= - \frac{dr}{\lambda(x)F(r,x)} + \dots, \tag{121}
\end{aligned}$$

where the ellipses are subleading terms in the hydrodynamic expansion. As we will see in the following section, hypersurfaces of constant ρ no longer coincide with hypersurfaces of constant r in the hydrodynamic regime.

⁷Notice that the relation (111) is the same as the relation one obtains starting from (52) in rescaled coordinates (9) with (53) due to the cancellation of factors in the denominator of the right-hand side of (109).

FIG. 1 (color online). The spacetime has past and future horizons $\mathcal{H}^-$ and $\mathcal{H}^+$ respectively. The dual fluid lives on a timelike surface Σ_c . Lines of constant t and constant r in the Eddington-Finkelstein coordinate system are shown.

B. Interpretation and dual field theory

In this section we turn to the interpretation in terms of renormalization group flow of the putative dual field theory. Let us step back from the specific examples to the generic metric ansatz (1) in which the induced metric $\gamma(r_c)$ on Σ_c is given in (2). The spacetime Penrose diagram is illustrated in Fig. 1.

In the putative fluid/gravity correspondence, the background metric for the fluid (and hence for the field theory) is $\gamma(r_c)$. Viewing r_c as an energy scale, it is manifest that this metric runs with the energy scale. In field theory language, suppose the field theory has couplings $g^a(\Lambda)$ which run with the energy scale Λ via their beta functions

$$\beta_{g^a} = \frac{\partial g^a(\Lambda)}{\partial \ln \Lambda}; \quad (122)$$

then it is usual to characterize the couplings in terms of a reference (cutoff) energy scale Λ^o such that $g^a(\Lambda^o) \equiv g_o^a$. In the case at hand, the induced metric for the fluid effectively provides background couplings for the putative dual theory. The boundary condition on Σ_c imposes

$$\gamma(r_c)_{ab} = \Omega^2 \eta_{ab}; \quad (123)$$

i.e. at this “energy” scale the metric is conformally flat. Having fixed the metric at this reference point, the metric at a different energy scale is generically not conformally flat since the time and space components “run” differently. Just as in field theory, however, the choice of reference point is arbitrary: one can change $r_c \rightarrow r'_c$.

One can only provide a fluid/gravity interpretation if the fluid stress energy tensor is conserved⁸ and satisfies a thermodynamic relation with the temperature and entropy density. As many authors have pointed out, the Brown-York stress energy tensor defined in (29) is a natural candidate for the fluid energy momentum tensor as it is conserved. One has to be careful here, though, since a fluid stress energy tensor defined as

$$T_{ab}^F = C_1(r_c) T_{ab}^{\text{BY}} + C_2(r_c) \eta_{ab} \quad (124)$$

will be conserved for any choice of $(C_1(r_c), C_2(r_c))$. The function $C_2(r_c)$ drops out of the combination $(\rho + p)$ appearing in the thermodynamic relation but $C_1(r_c)$ is not restricted by conservation. We argued previously that $C_1(r_c)$ must scale homogeneously under a conformal rescaling of the induced metric so that the thermodynamic relation is satisfied for any choice of the conformal factor: $C_1(r_c) \rightarrow \Omega^{1-d} C_1(r_c)$ as $\eta_{ab} \rightarrow \Omega^2 \eta_{ab}$.

Clearly the thermodynamic relation is only satisfied for a specific choice of $C_1(r_c)$ (for fixed induced metric η_{ab}). The choice of $C_1(r_c)$ defines the holographic dictionary for the fluid. For $\Omega = 1$ the choice of $C_1(r_c)$ which is consistent with the thermodynamic relation is precisely $C_1(r_c) = 1$, in both the Rindler and the AdS cases. We will now show why this must be the case in *any* putative holographic correspondences (in which the bulk spacetime is describable by Einstein gravity with matter) satisfying a GKPW-type dictionary [62,63], i.e. a duality between the on-shell bulk action with “boundary condition” $\gamma(r_c)$ and the dual generating functional $W[\gamma(r_c)]$. We do not need to assume a negative cosmological constant or indeed any specific form for the bulk stress energy tensor.

The proof makes use of a Hamiltonian description of the bulk dynamics, following the same approach as in the Hamiltonian method of holographic renormalization [64]. One difference relative to the latter is that we will work with a finite cutoff and we will not need to look in detail at the renormalization. A second difference relative to Hamiltonian holographic renormalization is that we do not consider generic bulk solutions with given asymptotics; instead we restrict to the hydrodynamic regime in which the bulk solution is near to an equilibrium solution with horizon.

Let us consider a $(d+2)$ -dimensional manifold which can be radially foliated by hypersurfaces Σ_r of constant r . The metric can then be decomposed as

$$ds^2 = (N^2 + N_a N^a) dr^2 + 2 N_a dx^a dr + \gamma_{ab} dx^a dx^b, \quad (125)$$

⁸Strictly speaking the fluid stress energy tensor should satisfy an appropriate conservation equation but is not always conserved. The generalization to cases in which it is not conserved because of e.g. sources for currents is straightforward.

with N the shift and N_a the lapse. This metric reduces to the form used in the previous sections upon fixing the gauge such that $(N^2 + N^a N_a) = 0$, which is always possible since N_a is timelike; comparing with the (9), one sees that

$$N_a = -\frac{u_a}{\lambda}; \quad \gamma_{ab} = G(r)\eta_{ab} + (G(r) - F(r))u_a u_b. \quad (126)$$

However, one cannot fix this gauge before deriving the constraint equations. The action for Einstein gravity coupled to an arbitrary matter Lagrangian $\mathcal{L}_m$ (which may include a cosmological constant) can be written as

$$S = -\frac{1}{2k_{(d+2)}^2} \int d^{d+2}x \sqrt{-\gamma} N (\hat{R} + K^2 - K_{ab} K^{ab} - \mathcal{L}_m) \quad (127)$$

where $\hat{R}$ is the curvature of the metric γ_{ab} and K_{ab} is the extrinsic curvature of the hypersurface Σ_r . Note that in this rewriting of the bulk Einstein-Hilbert action one obtains a boundary term which precisely cancels the Gibbons-Hawking term; the variational problem for this action is well defined for given boundary data γ_{ab} . The canonical momentum conjugate to γ_{ab} is

$$\pi^{ab} = \frac{\delta L}{\delta(\partial_r \gamma^{ab})} = -\frac{\sqrt{-\gamma}}{2k_{(d+2)}^2} (K\gamma^{ab} - K^{ab}) \quad (128)$$

where the Lagrangian L is defined via $S = \int dr L$. Note that the momenta conjugate to the shift and lapse vanish, implying that the equations of motion are constraints. The crucial next step is to use the Hamilton-Jacobi formalism of mechanics to express the momenta on any given hypersurface as variations of the on-shell action with respect to the induced values of the fields on this surface, namely

$$\pi^{ab}(r_c) = \frac{\delta S_{\text{onshell}}}{\delta \gamma_{ab}(r_c)}. \quad (129)$$

Note that r_c is arbitrary, with the relation holding for any r_c provided that the radial coordinate is well defined. If a GKPW dictionary of the form given in [62,63] holds, then the on-shell action acts as the generating functional for background metric γ_{ab} and the corresponding stress energy tensor is defined as

$$T^{ab} = -\frac{2}{\sqrt{-\gamma}} \frac{\delta S_{\text{onshell}}}{\delta \gamma_{ab}(r_c)}. \quad (130)$$

Using the Hamilton-Jacobi relation this quantity becomes the Brown-York tensor, with constant prefactor

$$T^{ab} = \frac{1}{k_{(d+2)}^2} (K\gamma^{ab} - K^{ab}). \quad (131)$$

Therefore the identification of the on-shell action with the generating functional of the dual theory in a background metric γ_{ab} is equivalent to the stress energy tensor of the dual theory being the Brown-York tensor.

The only assumption so far is the existence of a radial foliation. If one further insists that such a foliation is by timelike hypersurfaces then it would be valid outside a horizon but clearly not applicable inside a horizon. Moreover, while the variational problem is well defined for the action (127) given the metric on the bounding hypersurface, the variational problem would be equally well posed if one added to the action boundary terms $S_B[\gamma]$ depending only on quantities intrinsic to the induced geometry. The corresponding stress energy tensor would then become

$$T^{ab} \rightarrow T^{ab} - \frac{2}{\sqrt{-\gamma}} \frac{\delta S_B[\gamma]}{\delta \gamma_{ab}}. \quad (132)$$

The boundary terms are uniquely determined in AdS/CFT when one takes the conformal class of the metric to be fixed as one takes the boundary to infinity and these terms are equivalent to the counterterms needed to obtain finite renormalized quantities. At finite r_c there is no natural way to fix the ambiguity with a generic bulk solution but, as we saw earlier, if we restrict to the hydrodynamic regime with the induced metric being flat, the ambiguity does not affect the thermodynamic relation. If the boundary metric for the dual theory is $\tilde{\gamma}_{ab} = \Omega^2 \gamma_{ab}$ then

$$T_{ab}^{\tilde{\gamma}} \equiv -\frac{2}{\sqrt{-\tilde{\gamma}}} \frac{\delta S_{\text{onshell}}}{\delta \tilde{\gamma}^{ab}(r_c)} = \Omega^{1-d} T_{ab}^{\gamma}, \quad (133)$$

in accordance with the relation noted earlier.

V. HYDRODYNAMICS AND NEAR EQUILIBRIUM SOLUTIONS

In this section we will promote general seed equilibrium solutions to hydrodynamic solutions by allowing the fluid properties to become slowly varying. Following the discussion earlier, we consider the form (9) of the seed metric which we rewrite below for convenience:

$$ds^2 = -\frac{2}{\lambda} u_a dx^a dr + G(r) dx_a dx^a + (G(r) - F(r))(u_a dx^a)^2, \quad (134)$$

in which $G(r_c) = F(r_c) = 1$, while $F(r_H) = 0$ at the horizon $\mathcal{H}$.

In equilibrium one can always find a shifting and subsequent rescaling of the radial coordinate to set

$\lambda = 1$. The flat spacetime metric in static Rindler coordinates can for example be written in the form (134) with $\lambda = 1$ as

$$ds^2 = 2drdt - (1 + p(r - r_c))dt^2 + dx^i dx_i. \quad (135)$$

The identification of the pressure and energy density of the dual fluid to the Rindler geometry of [8] follows from (34)–(35) straightforwardly: the pressure is indeed the parameter p while the energy density is zero.

Scaling λ to one is generically not compatible with imposing that the induced metric on the cutoff hypersurface is Minkowski, however, and we will find it more convenient to retain a generic λ in what follows. For example, for the AdS black-brane geometry (52) the seed metric is conveniently expressed after rescaling of the field theory coordinates as

$$ds^2 = \frac{2dt dr}{\sqrt{h_c} r_c / L} - \frac{r^2 h(r)}{r_c^2 h_c} dt^2 + \frac{r^2}{r_c^2} dx^i dx_i, \quad (136)$$

in which we again define $h_c = h(r_c)$.

A. General hydrodynamic equations

In order to move to the hydrodynamic regime, one needs to promote the thermodynamic parameters to become slowly varying functions; see [1]. This can be achieved by writing

$$ds^2 = -2\lambda(x)^{-1} u_a(x) dx^a dr + (G(r, x)) \eta_{ab} + (G(r, x) - F(r, x)) u_a(x) u_b(x) dx^a dx^b, \quad (137)$$

such that

$$\begin{aligned} \partial_a u^b(x) &\sim \mathcal{O}(\epsilon); & \partial \lambda &\sim \mathcal{O}(\epsilon); \\ \partial_a F(r, x) &\sim \mathcal{O}(\epsilon); & \partial_a G(r, x) &\sim \mathcal{O}(\epsilon), \end{aligned} \quad (138)$$

with ϵ small. The inverse metric is given by

$$\begin{aligned} g^{rr} &= \lambda(x)^2 F(r, x); & g^{ra} &= \lambda(x) u^a(x); \\ g^{ab} &= (G(r, x))^{-1} (\eta^{ab} + u^a u^b) \equiv (G(r, x))^{-1} h^{ab}. \end{aligned} \quad (139)$$

By construction this generalization preserves the induced metric on Σ_c and satisfies the Einstein plus matter equations to leading order in ϵ with the fluid parameters as given above. To any order $n \geq 1$ one will need to correct the metric by terms $g_{\mu\nu}^{(n)}$ such that the Einstein equations are still satisfied. Conservation of the Brown-York stress tensor on Σ_c to leading order in gradients implies

$$\begin{aligned} (p + \rho) D^a u_a &= -D\rho; \\ (p + \rho) a_c &= -D_c^\perp p, \end{aligned} \quad (140)$$

where $D_a^\perp \equiv h_a^b \partial_b$, $D \equiv u^a \partial_a$ and the acceleration $a_c = D u_c$. Note that the Rindler fluid had the property that the equilibrium energy density vanishes, and thus the fluid was incompressible to leading order, but this property is not in general satisfied.

Supposing that one weights derivatives such that $\partial_r \sim 1$ and $\partial_a \sim \epsilon$, if one adds a piece $g_{\mu\nu}^{(n)}$ to the metric at order ϵ^n then one can compute the associated change in the Ricci tensor at order ϵ^n to be $\delta R_{\mu\nu}^{(n)}$. This is computed using the usual linearized formula

$$\begin{aligned} \delta R_{\mu\nu}^{(n)} &= \frac{1}{2} (\nabla^\lambda \nabla_\mu g_{\nu\lambda}^{(n)} + \nabla^\lambda \nabla_\nu g_{\mu\lambda}^{(n)} + \\ &\quad - \nabla^\lambda \nabla_\lambda g_{\mu\nu}^{(n)} - \nabla_\mu \nabla_\nu \text{tr}(g^{(n)})), \end{aligned} \quad (141)$$

with ∇ evaluated using the leading order metric given above. Note that, since one needs to retain terms in the covariant derivative at order ϵ^0 , only radial derivatives need to be retained.

Order by order we must require the additional terms in the metric to be such that the Einstein equations are satisfied. Defining $\hat{R}_{\mu\nu}^{(n)}$ as the part of the Ricci tensor corresponding to $g^{(n-1)}$ due to ∂_a derivatives and $\delta R_{\mu\nu}^{(n)}$ being the part of the Ricci tensor related to radial derivatives ∂_r of $g^{(n)}$, the Einstein equations at order n are

$$\hat{R}_{\mu\nu}^{(n)} + \delta R_{\mu\nu}^{(n)} - \frac{1}{2} \sum_{k=0}^n g_{\mu\nu}^{(k)} \hat{R}^{(n-k)} - \frac{1}{2} g_{\mu\nu}^{(0)} \delta R^{(n)} = \mathcal{T}_{\mu\nu}^{(n)}, \quad (142)$$

where the Ricci scalar at each order is given by

$$\hat{R}^{(n)} + \delta R^{(n)} = \sum_{k=0}^n \hat{R}_{\alpha\beta}^{(k)} g^{(n-k)\alpha\beta} + \delta R_{\alpha\beta}^{(n)} g^{(0)\alpha\beta}, \quad (143)$$

and the inverse metric up to order k is defined in the way to assure that the trace of the metric is always the same $\text{tr}(g) = d + 2$; for example at first order it is

$$g^{(1)\mu\nu} = -g^{(0)\mu\rho} g^{(0)\nu\sigma} g_{\rho\sigma}^{(1)}. \quad (144)$$

Conditions (142) can be then rewritten in a more compact way as

$$\begin{aligned} \hat{R}_{\mu\nu}^{(n)} + \delta R_{\mu\nu}^{(n)} &= \bar{\mathcal{T}}_{\mu\nu}^{(n)}, \\ \bar{\mathcal{T}}_{\mu\nu}^{(n)} &= \mathcal{T}_{\mu\nu}^{(n)} - \frac{1}{d} \sum_{k=0}^n g_{\mu\nu}^{(k)} \mathcal{T}^{(n-k)}, \end{aligned} \quad (145)$$

with

$$\mathcal{T}^{(n)} = \sum_{k=0}^n \mathcal{T}_{\alpha\beta}^{(k)} g^{(n-k)\alpha\beta}. \quad (146)$$

Imposing the natural gauge choice $g_{r\mu}^{(n)} = 0$ for $n \geq 1$ we obtain the following for the perturbations of the Ricci tensor induced by the addition of $g^{(n)}$:

$$\begin{aligned} \delta R_{rr}^{(n)} &= -\frac{1}{2} h^{ab} \partial_r^2 \left(\frac{1}{G} g_{ab}^{(n)} \right) - \frac{1}{2} \frac{G'}{G} h^{ab} \partial_r \left(\frac{1}{G} g_{ab}^{(n)} \right); \\ \lambda^{-1} \delta R_{ra}^{(n)} &= \frac{1}{2G^{d/2}} u^b \partial_r (G^{d/2} \partial_r g_{ab}^{(n)}) + \frac{1}{4} F' u_a h^{cd} \partial_r \left(\frac{1}{G} g_{cd}^{(n)} \right) \\ &\quad - \frac{1}{2G^{d/2}} u^c h_a^d \partial_r \left(\frac{G'}{G} G^{d/2} g_{cd}^{(n)} \right); \\ \lambda^{-2} \delta R_{ab}^{(n)} &= -\frac{1}{4} F (G' h_{ab} - F' u_a u_b) h^{cd} \partial_r \left(\frac{1}{G} g_{cd}^{(n)} \right) \\ &\quad - \frac{1}{2G^{d/2}} \partial_r (G^{d/2} F \partial_r g_{ab}^{(n)}) + \frac{G' F}{G} h_{(a}^c \partial_r g_{cb}^{(n)} \\ &\quad + \frac{F' G'}{G} u_{(a} h_{b)}^c u^d g_{cd}^{(n)} - F' u_{(a} u^c \partial_r g_{cb}^{(n)} \\ &\quad - \frac{1}{2} \frac{F G'^2}{G^2} h_{(a}^c h_{b)}^d g_{cd}^{(n)} - \frac{1}{2} \frac{G'^2}{G} h_{ab} u^c u^d g_{cd}^{(n)} \\ &\quad + \frac{1}{2G^{d/2}} u^c u^d \partial_r (G^{d/2} (G' h_{ab} - F' u_a u_b) g_{cd}^{(n)}), \end{aligned} \quad (147)$$

where primes denote radial derivatives. Moreover we find

$$\begin{aligned} \lambda^{-2} \delta R^{(n)} &= -\frac{1}{2} \frac{F}{G^{d/2}} \partial_r \left(G^{d/2} \partial_r \left(\frac{1}{G} g_{cd}^{(n)} h^{cd} \right) \right) \\ &\quad - \frac{1}{2} F' \partial_r \left(\frac{1}{G} g_{cd}^{(n)} h^{cd} \right) + \frac{G' F}{2G^2} \partial_r g_{cd}^{(n)} h^{cd} \\ &\quad - \frac{1}{2G^{d/2+1}} \partial_r (G^{d/2} F \partial_r g_{cd}^{(n)} h^{cd}) \\ &\quad + \frac{1}{G^{d/2}} \partial_r (G^{d/2} \partial_r g_{cd}^{(n)} u^c u^d) \\ &\quad + \frac{d}{2G^{d/2+1}} \partial_r (G^{d/2} G' g_{cd}^{(n)} u^c u^d) - \frac{d G'^2}{2G^2} g_{cd}^{(n)} u^c u^d, \end{aligned} \quad (148)$$

where we defined

$$\delta R^{(n)} = g^{(0)ab} \delta R_{ab}^{(n)}. \quad (149)$$

Notice that

$$\begin{aligned} &\lambda^{-2} \delta R_{\alpha\mu}^{(n)} n^\mu|_{\Sigma_c} \\ &= u_a u^c u^d g_{cd}^{(n)}|_{\Sigma_c} \left(\frac{d}{4} F'(r_c) G'(r_c) + F''(r_c) \right) \\ &\quad - h_a^c u^d g_{cd}^{(n)}|_{\Sigma_c} \left(G''(r_c) + \frac{(d-2)}{4} G'(r_c)^2 + \frac{1}{2} F'(r_c) G'(r_c) \right), \end{aligned} \quad (150)$$

which is identically zero when we impose the required Dirichlet boundary conditions on the hypersurface Σ_c , i.e. $g_{ab}^{(n)}|_{\Sigma_c} = 0$ with $n \geq 1$.

The Einstein equations can be used to solve for the different components of the metric perturbations, which at each gradient order can be decomposed in terms of a basis of linearly independent scalars, vectors and traceless symmetric tensors:

$$g_{ab}^{(n)} = \alpha^{(n)} u_a u_b + 2u_{(a} \beta_{b)}^{(n)} + \tilde{\gamma}_{ab}^{(n)} + \frac{1}{d} \gamma^{(n)} h_{ab} \quad (151)$$

with

$$u^a \beta_a^{(n)} = u^a \tilde{\gamma}_{ab}^{(n)} = \tilde{\gamma}_{ab}^{(n)} h^{ab} = 0. \quad (152)$$

Using (145) it is easy to show that the following equations must be satisfied:

$$\frac{1}{2} \partial_r^2 \left(\frac{1}{G} \gamma^{(n)} \right) + \frac{1}{2} \frac{G'}{G} \partial_r \left(\frac{1}{G} \gamma^{(n)} \right) + \tilde{T}_{rr}^{(n)} = 0, \quad (153)$$

$$\begin{aligned} &\frac{\lambda}{2} \partial_r^2 \beta_a^{(n)} + \frac{\lambda}{4} (d-2) \frac{G'}{G} \partial_r \beta_a^{(n)} - \lambda \left(\frac{1}{4} (d-2) \frac{G'^2}{G^2} + \frac{1}{2} \frac{G''}{G} \right) \beta_a^{(n)} + \\ &\quad - (\hat{R}_{rb}^{(n)} - \tilde{T}_{rb}^{(n)}) h_a^b = 0, \end{aligned} \quad (154)$$

$$\begin{aligned} &\frac{d}{2} \lambda^2 \frac{1}{G^{d/2}} \partial_r (G^{d/2} G' \alpha^{(n)}) - \frac{d}{2} \lambda^2 \frac{G'^2}{G} \alpha^{(n)} + \\ &\quad - \frac{\lambda^2}{2G^{d/2}} \partial_r (G^{d/2} F \partial_r \gamma^{(n)}) + \lambda^2 \frac{G' F}{G} \partial_r \gamma^{(n)} - \frac{\lambda^2 F G'^2}{2G^2} \gamma^{(n)} + \\ &\quad - \frac{d}{4} \lambda^2 F G' \partial_r \left(\frac{1}{G} \gamma^{(n)} \right) + (\hat{R}_{ab}^{(n)} - \tilde{T}_{ab}^{(n)}) h^{ab} = 0, \end{aligned} \quad (155)$$

$$\begin{aligned} &\frac{\lambda^2}{2} F \partial_r^2 \tilde{\gamma}_{ab}^{(n)} + \lambda^2 \left(\frac{1}{4} (d-4) \frac{F G'}{G} + \frac{1}{2} F' \right) \partial_r \tilde{\gamma}_{ab}^{(n)} \\ &\quad + \frac{\lambda^2 F G'^2}{2G^2} \tilde{\gamma}_{ab}^{(n)} - \hat{R}_{cd}^{(n)} h_a^c h_b^d + \frac{1}{d} \hat{R}_{cd}^{(n)} h^{cd} h_{ab} \\ &\quad + \left(\tilde{T}_{cd}^{(n)} h_a^c h_b^d - \frac{1}{d} \tilde{T}_{cd}^{(n)} h^{cd} h_{ab} \right) = 0. \end{aligned} \quad (156)$$

These equations are, respectively, the (rr) equation, the h^{ab} projection of the (ra) equation, the h^{ab} trace of the (ab) equation and the projection $(h_a^c h_b^d - 1/dh^{cd}h_{ab})$ of the (ab) equation. Additional, linearly dependent, equations may be obtained from other projections of the Einstein equations. For example, projecting the (ra) components of the Einstein equations onto u^a one obtains an additional equation for $\alpha^{(n)}$

$$\begin{aligned} \frac{1}{2}\lambda\partial_r^2\alpha^{(n)} + \lambda\frac{dG'}{4G}\partial_r\alpha^{(n)} - \frac{\lambda}{4}F'\partial_r\left(\frac{\gamma^{(n)}}{G}\right) \\ + (\hat{R}_{ra}^{(n)} - \bar{T}_{ra}^{(n)})u^a = 0. \end{aligned} \quad (157)$$

Since this equation is second order it is more convenient to use the first order equation (155). Similarly one can obtain an additional equation for $\beta^{(n)}$ from the projection $h_b^c u^a$ of the (ab) components of the Einstein equations.

The Bianchi identities at order n are

$$(\nabla_\mu G^{\mu\nu})^{(n)} = \sum_{k=0}^n \nabla_\mu^{(n-k)} G^{(k)\mu\nu} = 0. \quad (158)$$

Using the Einstein equations at each order and the conservation of the bulk stress energy tensor at order n , $(\nabla_\mu T^{\mu\nu})^{(n)} = 0$, the following identity holds:

$$\nabla_\mu^{(0)} G^{(n)\mu\nu} = \nabla_\mu^{(0)} T^{(n)\mu\nu}, \quad (159)$$

or equivalently

$$\nabla_\mu^{(0)} R^{(n)\mu\nu} = \nabla_\mu^{(0)} \bar{T}^{(n)\mu\nu}. \quad (160)$$

The independent (r) and (a) components of (160) are

$$\begin{aligned} \frac{1}{2}\lambda^4 F F' (R_{rr}^{(n)} - \bar{T}_{rr}^{(n)}) + \lambda^3 F' (R_{ra}^{(n)} - \bar{T}_{ra}^{(n)})u^a + \\ - \frac{1}{2}\lambda^2 \frac{F G'}{G^2} (R_{ab}^{(n)} - \bar{T}_{ab}^{(n)})h^{ab} \\ + \frac{\lambda^2 F}{G^{d/2}} \partial_r (G^{d/2} (\lambda^2 F (R_{rr}^{(n)} - \bar{T}_{rr}^{(n)}) + 2\lambda (R_{ra}^{(n)} - \bar{T}_{ra}^{(n)})u^a)) \\ + \lambda^2 \frac{1}{G^{d/2}} \partial_r (G^{d/2} (R_{ab}^{(n)} - \bar{T}_{ab}^{(n)})u^a u^b) = 0, \\ \frac{1}{G^{d/2}} \partial_r (G^{d/2} (\lambda F (R_{ar}^{(n)} - \bar{T}_{ar}^{(n)}) + (R_{ab}^{(n)} - \bar{T}_{ab}^{(n)})u^b)) = 0. \end{aligned} \quad (161)$$

From (148) and using the leading order equations of motion (21) one can show that the following expressions are identically satisfied:

$$\begin{aligned} \lambda F \delta R_{ar}^{(n)} u^a + \delta R_{ab}^{(n)} u^a u^b \\ = \left(-\frac{1}{d} T^{(0)} + \lambda T_{re}^{(0)} u^e \right) g_{ab}^{(n)} u^a u^b, \\ \lambda F \delta R_{ar}^{(n)} h_c^a + \delta R_{ab}^{(n)} u^b h_c^a \\ = \left(-\frac{1}{d} T^{(0)} + \frac{1}{dG} T_{ef}^{(0)} h^{ef} \right) g_{ab}^{(n)} u^b h_c^a. \end{aligned} \quad (162)$$

Using

$$\begin{aligned} \lambda F \bar{T}_{ar}^{(n)} + \bar{T}_{ab}^{(n)} u^b = \lambda F T_{ar}^{(n)} + T_{ab}^{(n)} u^b + \\ - \frac{1}{d} T^{(0)} g_{ab}^{(n)} u^b - \frac{1}{d} \sum_{k=1}^{n-1} g_{ab}^{(k)} u^b T^{(n-k)} \end{aligned} \quad (163)$$

Eq. (161) can be brought into the form:

$$\begin{aligned} \partial_r \left(G^{d/2} \left(\lambda F (\hat{R}_{ar}^{(n)} - T_{ar}^{(n)}) + (\hat{R}_{ab}^{(n)} - T_{ab}^{(n)})u^b \right. \right. \\ \left. \left. + \lambda T_{re}^{(0)} u^e g_{ab}^{(n)} u^b + \frac{1}{d} \sum_{k=1}^{n-1} g_{ab}^{(k)} u^b T^{(n-k)} \right) \right) u^a = 0, \\ \partial_r \left(G^{d/2} \left(\lambda F (\hat{R}_{ar}^{(n)} - T_{ar}^{(n)}) + (\hat{R}_{ab}^{(n)} - T_{ab}^{(n)})u^b \right. \right. \\ \left. \left. + \frac{1}{dG} T_{ef}^{(0)} h^{ef} g_{ab}^{(n)} u^b + \frac{1}{d} \sum_{k=1}^{n-1} g_{ab}^{(k)} u^b T^{(n-k)} \right) \right) h_c^a = 0. \end{aligned} \quad (164)$$

Integrating these conditions and evaluating them on Σ_c gives

$$(\lambda (\hat{R}_{ar}^{(n)} - T_{ar}^{(n)}) + (\hat{R}_{ab}^{(n)} - T_{ab}^{(n)})u^b)|_{\Sigma_c} = f_a^{(n)}(x)|_{\Sigma_c}, \quad (165)$$

where $f_a^{(n)}(x)$ arises as an integration constant.

The Gauss-Codazzi equations on Σ_c at order n are given by

$$\begin{aligned} \nabla^b T_{ab}^{(n)BY}|_{\Sigma_c} &= -2R_{a\mu}^{(n)} n^\mu|_{\Sigma_c} = -2(\hat{R}_{a\mu}^{(n)} + \delta R_{a\mu}^{(n)})|_{\Sigma_c} n^\mu \\ &= -2(\lambda \hat{R}_{ar}^{(n)} + \hat{R}_{ab}^{(n)} u^b)|_{\Sigma_c} \\ &= -2n^\mu T_{a\mu}^{(n)} - 2f_a^{(n)}(x)|_{\Sigma_c}. \end{aligned} \quad (166)$$

As discussed around (32), conservation of the fluid stress tensor requires that $T_{a\mu}^{(n)} n^\mu$ vanishes to all orders, which in turn requires that $T_{a\mu}^{(n)} n^\mu = 0$ to all orders n since n^μ does not change due to the required Dirichlet boundary conditions. If the fluid is not conserved then $T_{a\mu}^{(n)} n^\mu \neq 0$ characterizes this nonconservation. In both cases the integration constant arising from integrating the Bianchi

identities is therefore zero for the fluid stress energy tensor to satisfy the required conservation equation.

The extrinsic curvature at order n is given by

$$K_{ab}^{(n)} = \frac{1}{2}(\mathcal{L}_n g_{ab})|_{\Sigma_c} = \hat{K}_{ab}^{(n)} + \delta K_{ab}^{(n)}, \quad (167)$$

where again we divide it into two contributions: $\hat{K}_{ab}^{(n)}$ corresponding to contributions at order n coming from spacetime derivatives ∂_a of $g^{(n-1)}$ and $\delta K_{ab}^{(n)}$ coming from radial derivatives of $g^{(n)}$. Let us introduce the following notation for the velocity derivatives:

$$\theta = \partial_c u^c; \quad a_a = D u_a; \quad (168)$$

$$\mathcal{K}_{ab} = h_{(a}^c h_{b)}^d \partial_c u_d; \quad \sigma_{ab} = \mathcal{K}_{ab} - \frac{1}{d} \theta h_{ab}, \quad (169)$$

where as defined earlier, $D = u^c \nabla_c$. We obtain

$$\hat{K}_{ab}^{(1)} = \sigma_{ab} + \frac{1}{d} \theta h_{ab} - u_{(a} a_{b)} - u_{(a} \partial_{b)} \ln \lambda, \quad (170)$$

$$\hat{K}_{ab}^{(n)} = \frac{1}{2} D g_{ab}^{(n-1)}|_{\Sigma_c} \quad \text{with} \quad n > 1, \quad (171)$$

where we have used the Dirichlet boundary condition and the expression for the normal vector (27), and

$$\begin{aligned} \delta K_{ab}^{(n)} = \frac{1}{2} \lambda \partial_r g_{ab}^{(n)}|_{\Sigma_c} = \frac{1}{2} \lambda \left(\alpha^{(n)'}(r_c) u_a u_b + 2 \beta_{(a}^{(n)'}(r_c) u_{b)} \right. \\ \left. + \tilde{\gamma}_{ab}^{(n)'}(r_c) + \frac{1}{d} \gamma^{(n)'}(r_c) h_{ab} \right). \end{aligned} \quad (172)$$

The Brown-York stress energy tensor can also be split as

$$T_{ab}^{\text{BY}(n)} = \hat{T}_{ab}^{\text{BY}(n)} + \delta T_{ab}^{\text{BY}(n)}, \quad (173)$$

where again

$$\hat{T}_{ab}^{\text{BY}(n)} = 2(\hat{K}^{(n)} \eta_{ab} - \hat{K}_{ab}^{(n)}), \quad (174)$$

with

$$\hat{K}^{(n)} = \hat{K}_{ab}^{(n)} \eta^{ab}, \quad (175)$$

is the contribution coming from the $(n-1)$ th order metric, and

$$\delta T_{ab}^{\text{BY}(n)} = 2(\delta K_{ab}^{(n)} \eta_{ab} - \delta K_{ab}^{(n)}), \quad (176)$$

with

$$\delta K^{(n)} = \delta K_{ab}^{(n)} \eta^{ab}, \quad (177)$$

is the contribution coming from the correction of the metric at order n . The last part can be worked out formally giving

$$\begin{aligned} \lambda^{-1} \delta T_{ab}^{\text{BY}(n)} = & \left(-u_a u_b \gamma^{(n)'}(r_c) - 2 \beta_{(a}^{(n)'}(r_c) u_{b)} \right. \\ & + h_{ab} \left(-\alpha^{(n)'}(r_c) + \frac{(d-1)}{d} \gamma^{(n)'}(r_c) \right) \\ & \left. - \tilde{\gamma}_{ab}^{(n)'}(r_c) \right). \end{aligned} \quad (178)$$

We will work in Landau gauge for the fluid stress tensor

$$T_{ab}^{\text{F}(n)} u^a = 0; \quad n \geq 1. \quad (179)$$

Imposing this condition on the fluid stress energy tensor given in (124) gives two additional constraints order by order $n \geq 1$ on the Brown-York stress energy tensor

$$\begin{aligned} \lambda \gamma^{(n)'}(r_c) - \hat{T}_{ab}^{\text{BY}(n)} u^a u^b &= 0, \\ \lambda \beta_c^{(n)'}(r_c) + \hat{T}_{ab}^{\text{BY}(n)} u^a h_c^b &= 0, \end{aligned} \quad (180)$$

which follow from the two independent projections of the condition above (179), and we used the fact that $C_1(r_c) = 1$ for a flat metric on Σ_c and that $C_2(r_c)$ results only in a redefinition of the pressure and energy density.

B. General first order hydrodynamics

The Ricci tensor contribution coming from the seed metric is

$$\begin{aligned} \hat{R}_{rr}^{(1)} &= 0, \\ \hat{R}_{ra}^{(1)} &= u_a \left(\frac{G'}{2G} \partial_c u^c + \frac{d}{2G} D G' - \frac{d G'}{4 G^2} D G \right) \\ &\quad + \frac{d G'}{4 G} a_a - (d-1) \frac{1}{2G} D_a^\perp G' \\ &\quad + (d-1) \frac{G'}{2 G^2} D_a^\perp G - \frac{1}{4} d \frac{G'}{G} D_a^\perp \ln \lambda, \\ \lambda^{-1} \hat{R}_{ab}^{(1)} &= u_a u_b \left(\frac{1}{2} F' \partial_c u^c - \frac{d G'}{4 G} D F \right. \\ &\quad \left. + \frac{d F'}{4 G} D G - \frac{1}{2} d \frac{G' F}{G} D \ln \lambda \right) \\ &\quad + h_{ab} \left(-\frac{1}{2} G' \partial_c u^c - D G' - \frac{(d-2)}{2} \frac{G'}{G} D G \right) \\ &\quad + u_{(a} a_{b)} \left(F' + \frac{(d-2)}{2} \frac{G' F}{G} \right) \\ &\quad + u_{(a} D_{b)}^\perp F' + \frac{(d-2)}{2} \frac{G'}{G} u_{(a} D_{b)}^\perp F - \frac{d}{2} G' \mathcal{K}_{ab} \\ &\quad + u_{(a} D_{b)}^\perp \ln \lambda \left(F' + \frac{1}{2} (d-2) \frac{G' F}{G} \right). \end{aligned} \quad (181)$$

Recalling that

$$G(r_c) = F(r_c) = 1; \quad DG(r_c) = DF(r_c) = 0, \quad (182)$$

the momentum constraint $R_{a\mu}^{(1)} n^\mu|_{\Sigma_c} = (\hat{R}_{a\mu}^{(1)} + \delta R_{a\mu}^{(1)}) n^\mu|_{\Sigma_c} = 0$ evaluates into the ideal fluid equations of motion (140).

The Brown-York stress energy tensor contribution (174) arising from the seed metric (134) is given by

$$\begin{aligned} \hat{T}_{ab}^{\text{BY}(1)} = & -2\theta u_a u_b + 2h_{ab} \left(\frac{(d-1)}{d} \theta - D \ln \lambda \right) + \\ & -2\sigma_{ab} + 2u_{(a} a_{b)} + 2u_{(a} D_{b)}^\perp \ln \lambda, \end{aligned} \quad (183)$$

and the Landau gauge condition (180) becomes

$$\begin{aligned} \lambda \gamma^{(1)'}(r_c) &= -2\theta, \\ \lambda \beta_a^{(1)'}(r_c) &= a_a + D_a^\perp \ln \lambda. \end{aligned} \quad (184)$$

Hence the complete contribution to the Brown-York stress energy tensor (173) at first order in Landau gauge is given by

$$T_{ab}^{\text{BY}(1)} = -h_{ab}(2D \ln \lambda + \lambda \alpha^{(1)'}(r_c)) - 2\sigma_{ab} - \lambda \tilde{\gamma}_{ab}^{(1)'}(r_c). \quad (185)$$

Note that this result holds generally, regardless of the structure of the bulk stress energy tensor.

Consider first the case in which there is no matter. Then to first order in gradients there is only one independent scalar which may be chosen to be θ ; there is only one vector orthogonal to u^a , which we may choose as a_a ; the only symmetric traceless tensor orthogonal to u^a is σ_{ab} . The other scalars ($D\rho$, $D \ln p$) can be eliminated using the equation of state and the fluid equations, while the other vector $D_a^\perp \ln p$ can similarly be eliminated. Hence the dissipative part of the fluid stress energy tensor can be written as

$$T_{ab}^{\text{F}(1)} = -2\eta(r_c)\sigma_{ab} - \xi(r_c)\theta h_{ab}, \quad (186)$$

to first order in gradients, where

$$\eta(r_c)\sigma_{ab} = \left(\frac{1}{2} \lambda h_{ac} h_{bd} \tilde{\gamma}^{cd(1)'}(r_c) + \sigma_{ab} \right), \quad (187)$$

$$\xi(r_c)\theta = \lambda \alpha^{(1)'}(r_c) + 2D \ln \lambda, \quad (188)$$

define the shear viscosity $\eta(r_c)$ and the bulk viscosity $\xi(r_c)$ at the hypersurface Σ_c .

Notice that the shear over entropy ratio

$$\frac{\eta(r_c)}{s(r_c)} \sigma_{ab} = \frac{\frac{1}{2} \lambda h_{ac} h_{bd} \tilde{\gamma}^{cd(1)'}(r_c) + \sigma_{ab}}{4\pi G(r_H)^{d/2}}, \quad (189)$$

where we used (40), satisfies the universal value $\eta/s = 1/4\pi$ only if

$$\frac{1}{2} \lambda h_{ac} h_{bd} \tilde{\gamma}^{cd(1)'}(r_c) + \sigma_{ab} = G(r_H)^{d/2} \sigma_{ab}. \quad (190)$$

C. The cutoff AdS fluid, revisited

We will now consider the case of a negative cosmological constant, expanding around the asymptotically AdS black-brane geometry (52). The first step is to write the latter in the required form (134) through (53). One computes the hydrodynamic solution by promoting r_H and u_a to be slowly varying $r_H(x)$, $u_a(x)$. Since G is independent of both quantities $DG = D^\perp G = 0$, which considerably simplifies the formulas given above.

The bulk stress energy tensor is

$$T_{\mu\nu} = -\Lambda g_{\mu\nu}. \quad (191)$$

The condition for the Brown-York stress energy tensor (and hence the fluid stress energy tensor) to be conserved is identically satisfied at zeroth order since $T_{\mu\nu}^{(0)} n^\mu = 0$. Conservation at higher orders is guaranteed by the Dirichlet condition for the metric on Σ_c .

The reduced bulk stress energy tensor is

$$\bar{T}_{\mu\nu}^{(1)} = \frac{2}{d} \Lambda g_{\mu\nu}^{(1)} \quad (192)$$

which leads to

$$\begin{aligned} \bar{T}_{rr}^{(1)} &= 0; \quad \bar{T}_{ab}^{(1)} h^{ab} = \frac{2}{d} \Lambda \gamma^{(1)}; \\ \bar{T}_{ra}^{(1)} h_b^a &= 0; \quad \bar{T}_{ab}^{(1)} h_c^a h_d^b - \frac{1}{d} \bar{T}_{ab}^{(1)} h^{ab} h_{cd} = \frac{2}{d} \Lambda \tilde{\gamma}_{cd}^{(1)}. \end{aligned} \quad (193)$$

Using the conservation of the stress energy tensor (140) it is possible to trade derivatives of the horizon radius r_H with derivatives of the fluid velocities

$$\frac{\partial_a r_H}{r_H} = \left(\frac{1}{d} \theta u_a - \delta(r_c) a_a \right), \quad (194)$$

where

$$\delta(r_c) = \frac{2(1 - (r_H/r_c)^{d+1})}{2 + (d-1)(r_H/r_c)^{d+1}} = \frac{2h_c}{2h_c + (d+1)(1-h_c)}; \quad (195)$$

notice that when $r_c \rightarrow \infty$ we have $\delta(r_c) \rightarrow 1$ and one recovers the usual relation for conformal fluids (231). Equations (153)–(157) are

$$\partial_r^2 \left(\frac{r_c^2}{r^2} \gamma^{(1)} \right) + \frac{2}{r} \partial_r \left(\frac{r_c^2}{r^2} \gamma^{(1)} \right) = 0, \quad (196)$$

$$\begin{aligned} dh_c \frac{r}{L^2} \alpha^{(1)'} + h_c \frac{d(d-1)}{L^2} \alpha^{(1)} + \left(\frac{(d+1)}{L^2} + \frac{(d-2)}{L^2} h \right) \gamma^{(1)} \\ - \frac{r}{L^2} \left((d-1)h + \frac{1}{2} r h' \right) \gamma^{(1)'} + \\ - \frac{1}{2} \frac{r^2}{L^2} h \gamma^{(1)''} - 2d \frac{r}{r_c L} \sqrt{h_c} \theta = 0, \end{aligned} \quad (197)$$

$$\begin{aligned} \beta_a^{(1)''} + \frac{(d-2)}{r} \beta_a^{(1)'} - 2 \frac{(d-1)}{r^2} \beta_a^{(1)} + \\ - \frac{d}{r} \frac{L}{r_c \sqrt{h_c}} \delta(r_c) a_a = 0, \end{aligned} \quad (198)$$

$$\partial_r \left(r^{d+2} h(r) \partial_r \left(\tilde{\gamma}_{ab}^{(1)} \frac{L^2}{r^2} \right) \right) + 2d \sqrt{h_c} \frac{L^3 r^{d-1}}{r_c} \sigma_{ab} = 0. \quad (199)$$

The Landau gauge condition (184) on the stress tensor gives the following equations:

$$\gamma^{(1)'}(r_c) + \frac{2L}{r_c \sqrt{h_c}} \theta = 0, \quad (200)$$

$$\beta_a^{(1)'}(r_c) = \frac{2L}{r_c \sqrt{h_c}} \left(\frac{h_c + (d+1)(1-h_c)}{2h_c + (d+1)(1-h_c)} \right) a_a. \quad (201)$$

Solutions to Eqs. (196)–(199) with Dirichlet boundary conditions $\gamma^{(n)}(r_c) = \alpha^{(n)}(r_c) = \beta_a^{(n)}(r_c) = \tilde{\gamma}_{ab}^{(n)}(r_c) = 0$ are given by

$$\gamma^{(1)} = \frac{2L}{r_c \sqrt{h_c}} r \left(1 - \frac{r}{r_c} \right) \theta, \quad (202)$$

$$\begin{aligned} \alpha^{(1)} = \frac{L}{dh_c^{3/2}} \frac{r}{r_c} \left(-(d+1) \left(1 - \frac{r_c^d}{r^d} \right) + (d-1)h \right. \\ \left. + \left(2 - (d+1) \frac{r_c^d}{r^d} \right) h_c \right) \theta, \end{aligned} \quad (203)$$

$$\beta_a^{(1)} = - \frac{L \delta(r_c)}{r_c^2 h_c^{3/2}} r \left(r \left(\frac{r_c^{d+1}}{r^{d+1}} - 1 \right) + r_c \left(1 - \frac{r_c^d}{r^d} \right) h_c \right) a_a, \quad (204)$$

$$\tilde{\gamma}_{ab}^{(1)} = \frac{2L}{r_c r_H} \sqrt{h_c} r^2 \left(k(r) - k(r_c) + \frac{1}{(d+1)} \log h/h_c \right) \sigma_{ab}, \quad (205)$$

where

$$k(r) = \frac{r_H}{r} {}_2F_1 \left(1, \frac{1}{d+1}, 1 + \frac{1}{d+1}, \frac{r_H^{d+1}}{r^{d+1}} \right); \quad (206)$$

see Appendix A for details of the derivation. The fluid stress energy tensor (186) at first order is

$$T_{ab}^{F(1)} = -2\eta(r_c) \sigma_{ab} - \xi(r_c) \theta h_{ab}, \quad (207)$$

with shear and bulk viscosity given by

$$\eta(r_c) \sigma_{ab} = \left(\frac{1}{2} \frac{r_c}{L} \sqrt{h_c} \gamma_{ab}^{(1)'}(r_c) + \sigma_{ab} \right) = \frac{r_H^d}{r_c^d} \sigma_{ab}, \quad (208)$$

$$\xi(r_c) = \frac{(d+1)(1-h_c)}{d h_c} + \frac{r_c}{L} \sqrt{h_c} \alpha^{(1)'}(r_c) = 0. \quad (209)$$

Hence, although the fluid is non conformal due to non-conformal equation of state (48) giving a nonzero trace for the stress energy tensor, the bulk viscosity is vanishing. Given the entropy density $s(r_c) = 4\pi r_H^d / r_c^d$ the universal shear over entropy ratio bound is recovered at each hypersurface Σ_c :

$$\frac{\eta(r_c)}{s(r_c)} = \frac{1}{4\pi}, \quad (210)$$

confirming the results found previously for the nonrelativistic fluid dual to a finite cutoff hypersurface in AdS gravity [39] and the relativistic version of it [37]; see also [38]. Alternative derivations using renormalization group (RG) flows can be found in [5,26,29]; see also [49] for a derivation using linear response theory.

D. Relation to the conformal fluid

The finite cutoff solution can be connected to the usual AdS/CFT results if we first redefine the field theory coordinates

$$y^a = \frac{L}{r_c} x^a \quad (211)$$

in order to have a conformally flat metric on the boundary. The leading order metric now reads

$$ds^2 = -2 \frac{u_a}{\sqrt{h_c}} dy^a dr + \frac{r^2}{L^2} (h_{ab} - h/h_c u_a u_b) dy^a dy^b, \quad (212)$$

so that as $r_c \rightarrow \infty$ we have $h_c \rightarrow 1$ and the metric is the usual black-brane metric. The rescaling acts on the derivatives $\partial_a^x = \frac{L}{r_c} \partial_a^y$ with u_a unchanged; hence we have

$$\theta^x = \frac{L}{r_c} \theta^y; \quad a_a^x = \frac{L}{r_c} a_a^y; \quad \sigma_{ab}^x = \frac{L}{r_c} \sigma_{ab}^y, \quad (213)$$

and the perturbations (202)–(205) in the rescaled coordinates where we take into account $dx^a dx^b \rightarrow r_c^2/L^2 dy^a dy^b$ now read

$$\gamma^{y(1)} = \frac{2}{\sqrt{h_c}} r \left(1 - \frac{r}{r_c} \right) \theta^y, \quad (214)$$

$$\alpha^{y(1)} = \frac{1}{dh_c^{3/2}} r \left(-(d+1) \left(1 - \frac{r_c^d}{r^d} \right) + (d-1)h \right. \\ \left. + \left(2 - (d+1) \frac{r_c^d}{r^d} \right) h_c \right) \theta^y, \quad (215)$$

$$\beta_a^{y(1)} = -\frac{\delta(r_c)}{r_c h_c^{3/2}} r \left(r \left(\frac{r_c^{d+1}}{r^{d+1}} - 1 \right) + r_c \left(1 - \frac{r_c^d}{r^d} \right) h_c \right) a_a^y, \quad (216)$$

$$\tilde{\gamma}_{ab}^{y(1)} = \frac{2}{r_H} \sqrt{h_c} r^2 \left(k(r) - k(r_c) + \frac{1}{(d+1)} \log h/h_c \right) \sigma_{ab}^y. \quad (217)$$

The limit $r_c \rightarrow \infty$ gives now

$$\gamma^{y(1)} \rightarrow 2r\theta^y, \quad (218)$$

$$\alpha^{y(1)} \rightarrow \frac{r}{d} (d-1)(h-1)\theta^y \quad (219)$$

$$\beta_a^{y(1)} \rightarrow -ra_a^y, \quad (220)$$

$$\tilde{\gamma}_{ab}^{y(1)} \rightarrow 2 \frac{r^2}{r_H} \left(k(r) - k(\infty) + \frac{1}{(d+1)} \log h \right) \sigma_{ab}^y \\ = 2 \frac{r^2}{r_H} F(r/r_H) \sigma_{ab}^y, \quad (221)$$

where asymptotically $F(x) \sim \frac{1}{x} - \frac{1}{(d+1)x^{d+1}}$. Notice that the first order perturbation of the AdS black-brane metric is given in [1] as

$$ds^{(1)2} = 2 \frac{r^2}{r_H} F(r/r_H) \sigma_{ab} dy^a dy^b + \frac{2}{d} r \theta^y u_a u_b dy^a dy^b + \\ - 2ra_{(a}^y u_{b)} dy^a dy^b. \quad (222)$$

Relative to the metric perturbation given above the coefficients in the vector and tensor sector agree but those in the scalar sector do not. However, the two metrics are connected by the following diffeomorphism: consider a shift of the radial coordinate r such that

$$r \rightarrow r - \frac{1}{d} \theta^y. \quad (223)$$

Working to first order in gradients this results in a shift

$$\delta\gamma^{y(1)} = -2r\theta^y; \quad \delta\alpha^{y(1)} = \frac{r\theta^y}{d} (2 - (d-1)(h-1)), \quad (224)$$

thereby bringing the metric into the form given in [1].

The shear and bulk viscosity of the dual theory on the boundary can be obtained directly from (208)–(209) according to the prescription (133) by⁹

$$\eta^{\text{CFT}} \sigma_{ab}^y = \lim_{r_c \rightarrow \infty} r_c^{d-1} \eta(r_c) r_c \sigma_{ab}^y = r_H^d \sigma_{ab}^y, \\ \xi^{\text{CFT}} = \lim_{r_c \rightarrow \infty} r_c^{d-1} \xi(r_c) = 0. \quad (225)$$

Hence, the stress energy tensor at finite cutoff reproduces the usual AdS/CFT results as the cutoff is taken to the boundary.

The same result can be obtained directly from the metric perturbation at infinity (218)–(221) and using the usual AdS/CFT prescription (106). Since the metric on the boundary is (conformally) flat the dual fluid stress energy tensor is

$$\langle T_{ab}^{\text{CFT}} \rangle = \lim_{R \rightarrow \infty} R^{d-1} (T_{ab}^{\text{BY}} - 2d\gamma_{ab}), \quad (226)$$

where the Brown-York stress energy tensor is given by

$$T_{ab}^{\text{BY}(0)} = 2(K^{(0)} \gamma_{ab}^{(0)} - K_{ab}^{(0)}), \\ T_{ab}^{\text{BY}(1)} = 2(K^{(0)} \gamma_{ab}^{(1)} + K^{(1)} \gamma_{ab}^{(0)} - K_{ab}^{(1)}), \quad (227)$$

and the extrinsic curvature is computed at a finite cutoff surface Σ_R giving

$$K_{ab}^{(0)} = \frac{1}{2} n^{r(0)} \partial_r g_{ab}^{(0)}|_R, \\ K_{ab}^{(1)} = \frac{1}{2} n^{r(0)} \partial_r g_{ab}^{(1)}|_R + \frac{1}{2} n^{r(1)} \partial_r g_{ab}^{(0)}|_R \\ + \frac{1}{2} n^{c(0)} \partial_c g_{ab}^{(0)}|_R + g_{(a\mu} \partial_{b)}^{(0)} n^{\mu(0)}|_R, \\ K^{(0)} = K_{ab}^{(0)} \gamma^{ab(0)}, \\ K^{(1)} = K_{ab}^{(1)} \gamma^{ab(0)} + K_{ab}^{(0)} \gamma^{ab(1)}. \quad (228)$$

The induced metric on the hypersurface Σ_R is generically nonflat since

$$\gamma_{ab}^{(0)} = R^2 (h_{ab} - h(R) u_a u_b), \\ \gamma_{ab}^{(1)} = \frac{(d-1)}{d} (h(R) - 1) R \theta^y u_a u_b - 2R a_{(a}^y u_{b)} \\ + 2 \frac{R^2}{r_H} F(R/r_H) \sigma_{ab}^y + \frac{2}{d} R \theta^y h_{ab}, \\ \gamma^{ab(1)} = -\gamma^{ac(0)} \gamma^{bd(0)} \gamma_{cd}^{(1)}, \quad (229)$$

⁹We take $L = 1$ for notational simplicity.

giving nontrivial contributions to the normal vector up to and including order 1

$$\begin{aligned}\vec{n}^{(0)} &= R\sqrt{h(R)}\partial_r + \frac{1}{R\sqrt{h(R)}}u^a\partial_a, \\ \vec{n}^{(1)} &= -\frac{1}{2}\frac{(d-1)h(R)-1}{d}\frac{\theta^y\partial_r}{\sqrt{h(R)}} \\ &\quad + \frac{1}{R^2\sqrt{h(R)}}\left(\frac{1}{2}\frac{(d-1)(h(R)-1)}{d}\theta^y u^a - a^{(y)a}\right)\partial_a.\end{aligned}\quad (230)$$

Considering everything together and using the leading order equations of motion to relate derivatives of the horizon radius r_H to derivatives of u_a

$$\frac{\partial_a r_H}{r_H} = \frac{1}{d}\theta^y u_a - a_a, \quad (231)$$

we obtain the fluid stress energy tensor dual to a black-brane metric in AdS spacetime:

$$\langle T_{ab}^{\text{CFT}} \rangle = p h_{ab} + \rho u_a u_b - 2\eta \sigma_{ab} - 2\xi \theta^y h_{ab}, \quad (232)$$

with

$$p = r_H^{d+1}; \quad \rho = d r_H^{d+1}; \quad \eta = r_H^d; \quad \xi = 0. \quad (233)$$

E. UV field theory interpretation

The Dirichlet boundary condition on a finite cutoff hypersurface Σ_c necessarily leads to a non-Dirichlet boundary condition at the boundary. The aim of this section is to explore the interpretation of the fluid on the cutoff surface as a state in a deformation of the ultraviolet conformal field theory on the boundary. The strategy is to look at the solution (214)–(217) near the spacetime boundary by sending $r \rightarrow \infty$, changing to Fefferman-Graham coordinates. Using the standard AdS/CFT dictionary one can thereby show how the original UV CFT has been deformed.

The black-brane metric in Eddington-Finkelstein coordinates up to order 1 in the hydrodynamic expansion is

$$\begin{aligned}ds^2 &= -2\frac{u_a}{\sqrt{h_c}}dy^a dr + G_{ab}(y, r)dy^a dy^b, \\ G_{ab}^{(0)}(y, r) &= r^2(h_{ab} - h/h_c u_a u_b), \\ G_{ab}^{(1)}(y, r) &= \alpha^{(1)}\frac{1}{d}\theta u_a u_b + 2\beta^{(1)}a_{(a}u_{b)} \\ &\quad + \tilde{\gamma}^{(1)}\sigma_{ab} + \gamma^{(1)}\frac{1}{d}\theta h_{ab},\end{aligned}\quad (234)$$

where the coefficients in $G_{ab}^{(1)}$ are given by (214)–(217) with the obvious notational redefinition

$$\alpha^{(1)} \rightarrow \alpha^{(1)}\frac{1}{d}\theta; \quad \beta_a^{(1)} \rightarrow \beta^{(1)}a_a; \quad \tilde{\gamma}_{ab}^{(1)} \rightarrow \tilde{\gamma}^{(1)}\sigma_{ab}, \quad (235)$$

and we have again set $L = 1$ for convenience. This metric can be rewritten in the Fefferman-Graham form

$$ds^2 = \frac{d\rho^2}{\rho^2} + \frac{1}{\rho^2}g(z, \rho)_{ab}dz^a dz^b, \quad (236)$$

by requiring the following transformation equations to be satisfied order by order for the variables $\rho(r, y)$, $z^a(r, y)$ and the metric $g_{ab}(\rho, z)$:

$$\begin{aligned}(\partial_r \rho)^2 + g_{ab}(z, \rho)\partial_r z^a \partial_r z^b &= 0, \\ (\partial_r \rho)(\partial_a \rho) + g_{cd}(z, \rho)\partial_r z^c \partial_a z^d &= -\frac{u_a}{\sqrt{h_c}}\rho^2, \\ (\partial_a \rho)(\partial_b \rho) + g_{cd}(z, \rho)\partial_a z^c \partial_b z^d &= \rho^2 G_{ab}(y, r).\end{aligned}\quad (237)$$

At order zero the change of variables to bring the metric (234) into Fefferman-Graham form (236) with

$$\begin{aligned}g(z, \rho)_{ab}^{(0)} &= A(\rho)\left(h_{ab} - \frac{h(r(\rho))}{h_c}u_a u_b\right), \\ A(\rho) &= \left(1 + \frac{1}{4}(r_H \rho)^{d+1}\right)^{\frac{4}{d+1}},\end{aligned}\quad (238)$$

is

$$r^{(0)}(\rho) = \frac{1}{\rho}\sqrt{A(\rho)}; \quad y^{(0)a}(z, \rho) = z^a - k(r(\rho))u^a, \quad (239)$$

with

$$\begin{aligned}k(r) &= \frac{\sqrt{h_c}}{r} {}_2F_1\left(1, \frac{1}{d+1}, 1 + \frac{1}{d+1}, \frac{r_H^{d+1}}{r^{d+1}}\right), \\ \partial_r k(r) &= -\frac{\sqrt{h_c}}{r^2 h(r)}.\end{aligned}\quad (240)$$

The inverse transformation is given by

$$\begin{aligned}\rho &= \frac{1}{r}\left(\frac{2}{1 + \sqrt{h(r)}}\right)^{\frac{2}{d+1}} = \frac{1}{r}\sqrt{A(\rho(r))}, \\ z^a(y, r) &= y^a + k(r)u^a.\end{aligned}\quad (241)$$

At first order we can solve Eq. (237) using the following ansatz:

$$\begin{aligned}
\rho(y, r) &= \rho^{(0)}(y, r) + \rho^{(1)}(y, r), \\
z^a(y, r) &= z^{(0)a}(y, r) + z^{(1)a}(y, r) \\
&= z^{(0)a}(y, r) + \frac{1}{d} \theta(y) l(r) u^a(y) + m(r) a^a(y), \\
g_{ab}(z, \rho) &= g_{ab}^{(0)}(z, \rho) + g_{ab}^{(1)}(z, \rho). \tag{242}
\end{aligned}$$

The zeroth order metric (238) is both dependent on the Fefferman-Graham coordinates (z, ρ) and implicitly dependent on the Eddington-Finkelstein coordinate y through the dependence on $r_H(y)$:

$$g(z, \rho)_{ab}^{(0)} = A(y, \rho) \left(h_{ab}(z) - \frac{h(y, r(\rho))}{h_c(y)} u_a(z) u_b(z) \right). \tag{243}$$

The velocities and the metric can be Taylor expanded as follows:

$$\begin{aligned}
u^a(z) &= u^a(y) + k a^a(y), \\
g_{ab}(z, \rho)^{(0)} &= g_{ab}^{(0)}(y, r) + u^c(y) k(r) \partial_c g_{ab}(y, r) \\
&\quad + (\partial_r \rho^{(0)})^{-1} \rho^{(1)}(y, r) \partial_r g_{ab}^{(0)}(y, r) \\
&= A(\rho(r)) \left(h_{ab} - \frac{h}{h_c} u_a u_b \right) \\
&\quad + 2k(r) A(\rho(r)) \left(1 - \frac{h}{h_c} \right) a_{(a} u_{b)} + \dots, \tag{244}
\end{aligned}$$

where the last term in the metric can be ignored since we are ultimately interested in $g_{ab}(y, \rho)$,¹⁰ and we will have to perform the inverse transformation.

We use (194) and the following derivatives:

$$\begin{aligned}
\partial_r z^a(y, r) &= k'(r, y) u^a + l'(r) \frac{1}{d} \theta u^a + m'(r) a^a, \\
\partial_c z^a(y, r) &= \delta_c^a + \partial_c k(y, r) u^a + k(y, r) \partial_c u^a, \\
\partial_c k(y, r) &= \left(-k(y, r) + \frac{\sqrt{h_c}}{r h} + \right. \\
&\quad \left. - \frac{1}{2} (d+1) \frac{(1-h_c)}{h_c} k(y, r) \right) \frac{\partial_c r_H}{r_H}, \\
\partial_r \rho^{(0)}(y, r) &= -\frac{1}{r^2 \sqrt{h}} \sqrt{A(y, \rho(r))}, \\
\partial_c \rho^{(0)}(y, r) &= \frac{1}{r} \sqrt{A(y, \rho(r))} \frac{(1-\sqrt{h})}{\sqrt{h}} \frac{\partial_c r_H}{r_H}, \tag{245}
\end{aligned}$$

¹⁰The hydrodynamic expansion has been performed in transverse coordinates y and not in the Schwarzschild-type coordinates z .

where primes denote as usual derivatives with respect to the radial coordinate. After some manipulations the transformation to Fefferman-Graham form (242) is given by

$$\begin{aligned}
l'(r) &= \frac{1}{r} \sqrt{\frac{h_c}{h}} k' + k' k - 2k' \frac{1}{r} \frac{\sqrt{h_c}}{h} \\
&\quad + \frac{1}{2} k' k (d+1) \frac{(1-h_c)}{h_c} + \frac{1}{r^2} k' \frac{h_c}{h} \alpha^{(1)}, \\
m'(r) &= \frac{1}{r} k' \frac{(1-\sqrt{h_c})}{\sqrt{h_c}} \delta(r_c) + \frac{1}{r^2} k' \beta^{(1)} + k k', \tag{246}
\end{aligned}$$

and after redefining

$$\rho^{(1)}(y, r) = \frac{1}{r} \sqrt{A} X^{(1)}(y, r) \frac{1}{d} \theta \tag{247}$$

we have

$$X^{(1)'}(y, r) = k' \left(\frac{1}{2r} \sqrt{\frac{h_c}{h}} \alpha^{(1)} - \frac{(1-\sqrt{h})}{\sqrt{h}} \right), \tag{248}$$

which gives

$$X^{(1)}(y, r) = k + \frac{1}{r \sqrt{h_c h}} \left(\frac{r_c^d r}{r_H^{d+1}} (1-h_c) - 1 \right). \tag{249}$$

The black-brane metric up to order 1 in Fefferman-Graham coordinates can be parametrized by

$$\begin{aligned}
g_{ab}^{(1)}(y, \rho) &= \phi(y, r(\rho)) \frac{1}{d} \theta u_a u_b + \psi(y, r(\rho)) \frac{1}{d} \theta h_{ab} \\
&\quad + \Gamma(y, r(\rho)) \sigma_{ab} + 2\Sigma(y, r(\rho)) a_{(a} u_{b)}, \tag{250}
\end{aligned}$$

with

$$\begin{aligned}
\phi(y, r) &= 2Ak \frac{h}{h_c} - 2 \frac{A}{r} \frac{1}{\sqrt{h_c}} + Akh \frac{(1-h_c)}{h_c^2} (d+1) \\
&\quad + \frac{1}{r^2} A \alpha^{(1)} - 2AX^{(1)} \frac{h}{h_c}, \\
\psi(y, r) &= -2Ak + \frac{1}{r^2} A \gamma^{(1)} + 2AX^{(1)}, \\
\Sigma(y, r) &= +Ak \frac{h}{h_c} (1-\delta(r_c)) + \frac{1}{r} \frac{A}{\sqrt{h_c}} \delta(r_c) + \\
&\quad - \frac{1}{2} Akh \frac{(1-h_c)}{h_c^2} (d+1) \delta(r_c) + \frac{1}{r^2} A \beta^{(1)}, \\
\Gamma(y, r) &= -2Ak + \frac{A}{r^2} \tilde{\gamma}^{(1)}. \tag{251}
\end{aligned}$$

Notice that all the above expressions reduce to the expressions given earlier in [2] using the shifts (224) and then sending $r_c \rightarrow \infty$.

Using the zeroth order expression (239) into (251), using (214)–(217) and expanding the metric near the boundary of the spacetime, we can read off the leading radial term in the boundary metric

$$g_{ab}^{(0)}(y) = \eta_{ab} + (1 - 1/h_c)u_a u_b + \frac{2}{r_c h_c^{3/2}} \frac{1}{d} \theta u_a u_b + \frac{\delta(r_c)}{r_c h_c^{3/2}} a_{(a} u_{b)} + 2 \left(k(r_c) + \frac{1}{(d+1)} \frac{\sqrt{h_c}}{r_H} \ln h_c \right) \sigma_{ab} + \dots, \quad (252)$$

where the ellipses denote terms with higher powers of derivatives. Notice that after sending $r_c \rightarrow \infty$ the flat metric on the boundary is restored.

The precise interpretation of the fluid on the cutoff hypersurface in terms of the dual CFT can now be given using (252). The metric $g_{ab}^{(0)}$ characterizes the background metric for the dual CFT or, equivalently, the source for the CFT stress energy tensor. Whenever r_c is finite and hence $h_c \neq 1$, the metric $g_{ab}^{(0)}$ is not flat. Imposing a Dirichlet boundary condition on the finite cutoff surface Σ_c therefore translates into making a specific deformation of the original UV CFT: a nonflat background metric for the field theory fluid. Hence in terms of the UV CFT the fluid lives in a dynamical background metric, namely a metric which depends on the fluid velocity and temperature; a similar interpretation was given in [37].

Note that this deformation in the background metric appears to arise already at zeroth order in the hydrodynamic expansion. This was to be expected because, as discussed around (9) and (35), we started from a seed metric in which the time Killing vector is normalized to 1 at the cutoff hypersurface which implies that its norm at infinity is not canonical. One can therefore rescale the coordinates so that the zeroth order term in (252) is flat; this is achieved by rescaling the direction parallel to the velocity by a factor of $\sqrt{h_c}$ but leaving the directions perpendicular to the velocity unchanged. In terms of these rescaled coordinates, the background metric for the dual theory then becomes

$$g_{ab}^{(0)} = \eta_{ab} - \frac{2}{r_c h_c^{1/2}} \frac{1}{d} \theta u_a u_b + \frac{\delta(r_c)}{r_c h_c} a_{(a} u_{b)} + 2 \left(k(r_c) + \frac{1}{(d+1)} \frac{\sqrt{h_c}}{r_H} \ln h_c \right) \sigma_{ab} + \dots, \quad (253)$$

where the ellipses denote terms with higher powers of derivatives.

VI. CONNECTION TO THE MEMBRANE PARADIGM

Consider the limit in which the cutoff hypersurface Σ_c approaches the horizon $r_c \rightarrow r_H$. In the example of a

negative cosmological constant considered above the dual fluid has in this limit, as one would expect, the same properties of the Rindler fluid found in [8]. In particular we can show this by taking the $r_c \rightarrow r_H$ limit of the fluid stress energy tensor, giving

$$\eta(r_H) = 1, \quad (254)$$

with the usual shear over entropy universal bound being satisfied as $s = 1/4\pi$, and the bulk viscosity term vanishing.

In earlier literature another fluid has been associated to a hypersurface close to the horizon, namely the stretched horizon, within the so-called membrane paradigm [41–43]. The latter is an interpretation of the dynamics of a horizon in terms of a dissipative membrane fluid endowed with specific transport properties. However the two approaches are quite different even though both fluids are associated with a hypersurface close to a horizon. On the one hand, within the fluid/gravity duality approach, we have constructed a hydrodynamic solution using a derivative expansion. For consistency, Gauss-Codazzi equations representing the conservation of the Brown-York stress tensor have to be satisfied. We have seen in (133) that (up to appropriate conformal factors) the Brown-York stress tensor can be given a holographic interpretation as the stress energy tensor of the dual fluid associated with the finite cutoff hypersurface. The stress energy tensor has to be conserved at arbitrarily high order in the derivative expansion and therefore encodes all the transport coefficients.

On the other hand the membrane paradigm approach does not employ any derivative expansion around an equilibrium solution. Instead the membrane fluid equations are derived by reshuffling the Einstein equations and giving an *ad hoc* interpretation of them in terms of nonrelativistic dissipative Navier-Stokes equations.

In order to understand better the differences between the two approaches we will explore the membrane paradigm point of view in this section and derive the Damour-Navier-Stokes equation together with additional evolution equations for geometrical quantities defined on a d -dimensional spacelike foliation of a $(d+1)$ -dimensional hypersurface embedded in a $(d+2)$ -dimensional bulk spacetime. We will follow closely the approach of [50] by considering the case of a general hypersurface foliating the bulk spacetime, with the hypersurface not necessarily null and not necessarily close to the horizon; we then take the near horizon limit at the end.

A. Spacelike foliation of a generic hypersurface $\mathcal{H}$

Consider a generic $(d+1)$ -dimensional spacelike, time-like or null¹¹ hypersurface $\mathcal{H}$ and further foliate it by

¹¹In this formalism the hypersurface is general; however for our purposes we will later restrict it to be timelike.

d -dimensional closed, i.e. compact without boundary, spacelike hypersurfaces S_τ so that $\mathcal{H} = \tau \in \mathbb{R} S_\tau$. This means that the metric q induced by the spacetime metric g onto S_τ is positive definite and in components can be expressed

$$q_{\alpha\beta} = g_{\alpha\beta} + l_\alpha k_\beta + k_\alpha l_\beta, \quad (255)$$

where (l, k) is a pair of null vectors normal to S_τ satisfying

$$l \cdot l = 0; \quad k \cdot k = 0; \quad l \cdot k = -e^\sigma, \quad (256)$$

where σ is a positive number. It is possible to define a unique pair (l, k) by requiring

$$h = l - Ck; \quad l \cdot k = -1, \quad (257)$$

where h is the evolution vector tangent to $\mathcal{H}$ and orthogonal to S_τ at any point in $\mathcal{H}$ with the property

$$\mathcal{L}_h \tau = h^\mu \partial_\mu \tau = 1; \quad h \cdot h = 2C. \quad (258)$$

$\mathcal{L}_h$ can be viewed as the evolution operator along Σ_c : given an infinitesimal displacement described by the parameter $\delta\tau$, each point of S_τ is displaced into $S_{\tau+\delta\tau}$ by the vector $\delta\tau h$, and S_τ are then hypersurfaces Lie dragged by the evolution vector h . The character of h gives the character of the hypersurface $\mathcal{H}$; in particular if $C < 0$, then $\mathcal{H}$ and h are timelike.

The vectors (l, k) are collinear to the pair $(\tilde{l}, \tilde{k})$ associated to the dual-null foliation formalism [65]

$$l = A\tilde{l}; \quad k = B\tilde{k}, \quad (259)$$

where $(\tilde{l}, \tilde{k})$ can be defined as the null normal vectors to two families¹² of null hypersurfaces generated by outgoing and ingoing light rays orthogonally from S_τ :

$$\tilde{l} = -du; \quad \tilde{k} = -dv, \quad (260)$$

with u and v being parameters defining the dual-null foliations.

A natural additional vector that can be constructed out of (l, k) is

$$m = l + Ck; \quad m \cdot m = -2C; \quad m \cdot h = 0. \quad (261)$$

Notice that if h is timelike, m is necessarily spacelike and it defines the normal vector to the hypersurface $\mathcal{H}$, which, together with h spans the orthogonal space to S_τ .

Given a generic tensor T on the bulk spacetime, one can canonically define another tensor of the same covariance type q^*T using the projector

$$(q^*T)_{\beta_1 \dots \beta_n}^{\alpha_1 \dots \alpha_m} := q_{\mu_1}^{\alpha_1} \dots q_{\mu_m}^{\alpha_m} q_{\beta_1}^{\nu_1} \dots q_{\beta_n}^{\nu_n} T_{\nu_1 \dots \nu_n}^{\mu_1 \dots \mu_m}. \quad (262)$$

A tensorial field T for which $q^*T = T$ is said to be tangent to the surface S_τ . For any such tangent tensorial fields T we can define the covariant derivative on the spacelike surfaces S_τ

$$\mathcal{D}T = q^* \nabla T, \quad (263)$$

where clearly ∇ is the covariant derivative on the $(d+2)$ -dimensional bulk spacetime.

B. Extrinsic geometry of the spacelike surface S_τ

Given a vector field v orthogonal to the spacelike surface S_τ , the deformation tensor along this field is defined as

$$\Theta^{(v)} := q^*(\nabla v); \quad \Theta_{\alpha\beta}^{(v)} = q_\alpha^\nu q_\beta^\mu \nabla_\nu v_\mu, \quad (264)$$

measuring the variation of the metric in S_τ when the surface S_τ is displaced along v . The deformation tensor is symmetric and can be decomposed into a traceless symmetric shear tensor and a trace part

$$\sigma_{\alpha\beta}^{(v)} := \Theta_{\alpha\beta}^{(v)} - \frac{1}{d} \theta^{(v)} q_{\alpha\beta}; \quad \theta^{(v)} := q^{\mu\nu} \Theta_{\mu\nu}^{(v)}, \quad (265)$$

the latter measuring the change of the area element in S_τ when displaced by v .

The variation of the normal fields to S_τ with respect to each other is instead contained in the normal fundamental forms, which for the pair (l, k) can be written as

$$\Omega^{(l)} := \frac{1}{k \cdot l} k \cdot \nabla_q l; \quad \Omega_\alpha^{(l)} = \frac{1}{k_\rho l^\rho} k_\mu q_\alpha^\nu \nabla_\nu l^\mu; \quad (266)$$

$$\Omega^{(k)} := \frac{1}{k \cdot l} l \cdot \nabla_q k; \quad \Omega_\alpha^{(k)} = \frac{1}{k_\rho l^\rho} l_\mu q_\alpha^\nu \nabla_\nu k^\mu, \quad (267)$$

with the important relation¹³

$$\Omega^{(k)} = -\Omega^{(l)} + \mathcal{D}\sigma. \quad (268)$$

The extrinsic curvature can be defined out of the shape tensors along k and l as follows:

$$\mathcal{K}_{\beta\gamma}^\alpha = k^\alpha \Theta_{\beta\gamma}^{(l)} + l^\alpha \Theta_{\beta\gamma}^{(k)}. \quad (269)$$

The extrinsic curvature together with the normal fundamental forms are the sufficient quantities to describe the extrinsic geometry of the spacelike surfaces S_τ .

¹²These two families can be uniquely defined if the hypersurface $\mathcal{H}$ is spacelike or timelike, but there is an arbitrariness in the case $\mathcal{H}$ is null.

¹³For completeness we have reported the general equation; however since we will always use the definition (257), we can set $\sigma = 0$.

C. Kinematics of the spacelike surfaces S_τ

Covariant derivatives of the normal vectors l and k can be decomposed using quantities defined on the spacelike surfaces S_τ after using the projector (255):

$$\nabla_\alpha l_\beta = \Theta_{\alpha\beta}^{(l)} + \Omega_\alpha^{(l)} l_\beta - l_\alpha \nabla_k l_\beta - \nu_{(l)} k_\alpha l_\beta, \quad (270)$$

$$\nabla_\alpha k_\beta = \Theta_{\alpha\beta}^{(k)} - \Omega_\alpha^{(l)} k_\beta - k_\alpha \nabla_l k_\beta - \nu_{(k)} l_\alpha k_\beta, \quad (271)$$

where we have used Eqs. (259)–(260) to derive

$$\nabla_l l = \nu_{(l)} l; \quad \nu_{(l)} := \mathcal{L}_l \ln A; \quad (272)$$

$$\nabla_k k = \nu_{(k)} k; \quad \nu_{(k)} := \mathcal{L}_k \ln B. \quad (273)$$

Combining (270)–(271) and using the definitions (257) and (261) we can derive the covariant derivatives for m and h

$$\begin{aligned} \nabla_\alpha m_\beta &= \Theta_{\alpha\beta}^{(m)} + \Omega_\alpha^{(l)} h_\beta - l_\alpha \nabla_k l_\beta - \nu_{(l)} k_\alpha l_\beta \\ &\quad + (\nabla_\alpha C) k_\beta - C k_\alpha \nabla_l k_\beta - C \nu_{(k)} l_\alpha k_\beta, \end{aligned} \quad (274)$$

$$\begin{aligned} \nabla_\alpha h_\beta &= \Theta_{\alpha\beta}^{(h)} + \Omega_\alpha^{(l)} m_\beta - l_\alpha \nabla_k l_\beta - \nu_{(l)} k_\alpha l_\beta + \\ &\quad - (\nabla_\alpha C) k_\beta + C k_\alpha \nabla_l k_\beta + C \nu_{(k)} l_\alpha k_\beta, \end{aligned} \quad (275)$$

where we used

$$\Theta^{(m)} = \Theta^{(l)} + C\Theta^{(k)}; \quad \Theta^{(h)} = \Theta^{(l)} - C\Theta^{(k)}, \quad (276)$$

which follow straightforwardly from definition (264).

D. Dynamics of the spacelike surfaces S_τ

Having derived the expressions for the first derivatives of the vector fields m and h , we can now manipulate the second order derivatives using the Ricci identity, which for a generic vector field v is written as

$$R_{\rho\mu\nu}^\gamma v^\rho = (\nabla_\mu \nabla_\nu - \nabla_\nu \nabla_\mu) v^\gamma, \quad (277)$$

to derive evolution equations along m and h for the quantities defined on the spacelike hypersurfaces S_τ . Moreover, requiring the metric to be a solution of Einstein equations one can always trade the Ricci tensor for the trace subtracted bulk stress tensor

$$R_{\mu\nu} = \tilde{T}_{\mu\nu}, \quad (278)$$

where we have used the same notation as in the earlier sections. There are as many equations as there are many independent ways to project the Einstein equations along m , h and q . Some of the equations are listed below for illustration and we refer to Appendix B for details of their derivation. Projection along q and m results in the generalized Damour-Navier-Stokes equation as obtained previously in [50]:

$$\begin{aligned} q^* \mathcal{L}_h \Omega_\alpha^{(l)} + \theta^{(l)} \Omega_\alpha^{(l)} \\ = -\mathcal{D}_\mu \sigma_\alpha^{(m)\mu} + \frac{(d-1)}{d} \mathcal{D}_\alpha \theta^{(m)} \\ + \mathcal{D}_\alpha (\nu_{(l)} + C \nu_{(k)}) - \theta^{(k)} \mathcal{D}_\alpha C + q^* \tilde{T}_{\mu\alpha} m^\mu, \end{aligned} \quad (279)$$

which describes the evolution of the normal fundamental tensor $\Omega_\alpha^{(l)}$ along the vector field h . Other equations can be considered; e.g. the evolution equation for $\theta^{(m)}$ along m can be obtained by projecting twice along m ,

$$\begin{aligned} \nabla_m \theta^{(m)} + \nabla_m (\nu_{(l)} + C \nu_{(k)}) + \Theta_{\alpha\beta}^{(m)} \Theta^{(m)\alpha\beta} + \\ - \nabla_l \nu_{(l)} - \nu_{(l)} \theta^{(l)} - 2C \Omega^{(l)\alpha} \mathcal{D}_\alpha \ln A - (\theta^{(k)} + \nu_{(k)}) \nabla_m C + \\ - C \nabla_\alpha (\nabla_k l^\alpha + \nabla_l k^\alpha) + 4C \Omega^{(l)\alpha} \Omega_\alpha^{(l)} - 2C \nu_{(l)} \nu_{(k)} + \\ - C^2 \nu_{(k)} \theta^{(k)} - C^2 \nabla_k \nu_{(k)} + \tilde{T}_{\mu\nu} m^\mu m^\nu = 0, \end{aligned} \quad (280)$$

or the evolution equation of $\theta^{(m)}$ along h by projecting along h and m ,

$$\begin{aligned} \mathcal{L}_h \theta^{(m)} + \mathcal{L}_h (\nu_{(l)} + C \nu_{(k)}) + \Theta_{\alpha\beta}^{(h)} \Theta^{(m)\alpha\beta} + \\ - \nabla_l \nu_{(l)} - \nu_{(l)} \theta^{(l)} - (\theta^{(k)} + \nu_{(k)}) \mathcal{L}_h C \\ + C \nabla_\alpha (\nabla_k l^\alpha - \nabla_l k^\alpha) + C \nu_{(k)} \theta^{(k)} \\ + C^2 \nabla_k \nu_{(k)} + \tilde{T}_{\mu\nu} m^\mu h^\nu = 0. \end{aligned} \quad (281)$$

An example of a tensorial equation is the evolution equation of the shape tensor $\Theta_{\alpha\beta}^{(m)}$ which is

$$\begin{aligned} q^* \mathcal{L}_h \Theta_{\alpha\beta}^{(m)} &= \Theta_{\alpha\mu}^{(m)} \Theta_\beta^{(h)\mu} + \nu_{(l)} \Theta_{\alpha\beta}^{(l)} + C \Omega_\alpha \mathcal{D}_\beta \ln A \\ &\quad + \Theta_{\alpha\beta}^{(k)} \mathcal{L}_h C - C \nabla_\mu (\nabla_k l_\nu - \nabla_l k_\nu) q^\mu q_\beta^\nu + \\ &\quad - C^2 \nu_{(k)} \Theta_{\alpha\beta}^{(k)} + h^\nu R_{\rho\mu\nu\sigma} m^\mu q_\alpha^\sigma q_\beta^\rho. \end{aligned} \quad (282)$$

E. The null limit

The equations derived above are valid for a generic hypersurface $\mathcal{H}$. The limit in which the hypersurface $\mathcal{H}$ is null can be achieved by sending

$$C \rightarrow 0; \quad m \rightarrow l; \quad h \rightarrow l. \quad (283)$$

In this limit the null vector field l plays the double role of the tangent and the normal to the null hypersurface $\mathcal{H}$. In this way the system of equations derived above becomes degenerate and reproduces the usual equations for the dynamics of null hypersurfaces; see e.g. [66]. Equation (279) becomes the Damour-Navier-Stokes equation

$$\begin{aligned} q^* \mathcal{L}_l \Omega_\alpha^{(l)} + \theta^{(l)} \Omega_\alpha^{(l)} &= -\mathcal{D}_\mu \sigma_\alpha^{(l)\mu} + \frac{(d-1)}{d} \mathcal{D}_\alpha \theta^{(l)} \\ &\quad + \mathcal{D}_\alpha \nu_{(l)} + q^* \tilde{T}_{\mu\alpha} l^\mu, \end{aligned} \quad (284)$$

while Eqs. (280)–(281) become the so-called null Raychaudhuri equation

$$\nabla_l \theta^{(l)} + \Theta_{\alpha\beta}^{(l)} \Theta^{(l)\alpha\beta} - \nu_{(l)} \theta^{(l)} + \bar{T}_{\mu\nu} l^\mu l^\nu = 0, \quad (285)$$

and the tensorial equation (282) becomes the tidal force equation for $\Theta_{\alpha\beta}^{(l)}$

$$q^* \mathcal{L}_l \Theta_{\alpha\beta}^{(l)} = \Theta_{\alpha\mu}^{(l)} \Theta_{\beta}^{(l)\mu} + \nu_{(l)} \Theta_{\alpha\beta}^{(l)} + q^* (l^\nu R_{\beta\mu\nu\alpha} l^\mu). \quad (286)$$

The essence of the gravitational membrane paradigm is to reinterpret Eq. (284) formally in terms of a nonrelativistic dissipative Navier-Stokes equation

$$\mathcal{L}_l \mathcal{P}_\alpha + \theta \mathcal{P}_\alpha = -\partial_\alpha p + 2\eta \mathcal{D}_\beta \sigma_\alpha^{(l)\beta} + \xi \partial_\alpha \theta - f_\alpha \quad (287)$$

upon the identification

$$\begin{aligned} \mathcal{P}_\alpha &= -\Omega_\alpha^{(l)}; & \nu_{(l)} &= p; & \eta &= 1/2; \\ \xi &= -(d-1)/d; & q^* \bar{T}_{\mu\alpha} l^\mu &= f_\alpha, \end{aligned} \quad (288)$$

$\mathcal{P}_\alpha$ being the momentum surface density, p the fluid pressure, η and ξ the shear and bulk viscosity associated respectively with the shear tensor $\sigma_{\alpha\beta}^{(l)}$ and the expansion rate $\theta^{(l)}$, and f_α an external force surface density. Notice that the membrane fluid does not appear to be physical since it has a negative bulk viscosity.

F. Relation to the holographic fluid

This putative membrane fluid is not directly related to the near horizon Rindler fluid discussed in previous sections obtained from a holographic perspective, and here we depart from the interpretation given in [38]. Let us summarize the differences between the two setups. In the membrane approach we consider a generic timelike hypersurface for which we can take a null limit and we do not need to input specific information about the horizon nature of the null hypersurface. In the holographic approach we consider a timelike hypersurface outside a horizon; we fix the metric on this hypersurface.

In the membrane approach we work in a manifestly nonrelativistic formulation, in that we consider the $(d+1)$ -dimensional hypersurfaces to be foliated by spacelike d -dimensional hypersurfaces. The normal vectors to these spacelike hypersurfaces play an important role: it is their variation with respect to each other (a normal fundamental form) which is interpreted as the momentum density of the membrane fluid. Moreover, the shear and expansion of the spacelike surfaces along normal vectors is interpreted as the shear and expansion of the membrane fluid.

In the fluid/gravity approach, we can work either in relativistic or nonrelativistic formulations. In the earlier sections of this paper we have used the relativistic approach as this is computationally more efficient but one could

equally work with nonrelativistic expansions as in [6,7]. The holographic fluid properties are captured by the induced metric on the $(d+1)$ -dimensional timelike hypersurface, which acts as the background metric for the fluid, and by the extrinsic curvature of the hypersurface, which encodes the pressure, energy density and velocity of the fluid.

The putative membrane fluid is generally dissipative and the shear and bulk viscosity take universal values. Note however that if the chosen spacetime metric is what we have called a zeroth order equilibrium metric the shear tensor and the expansion rate of the horizon would vanish, so the dissipative terms would disappear.

In the holographic interpretation of fluid/gravity duality the zeroth order gravity solution represents a thermodynamic equilibrated state in which the behavior is non-dissipative. In order to get dissipative behavior at all it is necessary to perturb the thermodynamic solutions around equilibrium. This means that the existence of a family of solutions close to equilibrium thermodynamic solutions is an essential requirement to obtain hydrodynamic behavior. The shear and bulk viscosity depend on the system under consideration although η/s takes the well-known universal value of $1/4\pi$ in Einstein gravity.

In the fluid/gravity approach the Navier-Stokes equations (together with specific corrections) arise from working out the Einstein equations in a gradient expansion. All components of the Einstein equations are needed to work out the fluid equations. In the membrane paradigm only a specific projection of the Einstein equations is used to obtain the membrane fluid equations: remaining equations such as the tidal force equation do not have a natural interpretation in terms of fluid quantities.

VII. CONCLUSIONS

In this paper we have presented a construction of generic $(d+2)$ -dimensional near equilibrium metrics corresponding to the hydrodynamic regime of putative $(d+1)$ -dimensional holographic fluids associated with timelike hypersurfaces foliating a general (i.e. general bulk stress energy tensor) bulk spacetime. Using the method of Hamiltonian holographic renormalization we gave a prescription for the fluid stress energy tensor in the case of (conformally) flat Dirichlet boundary conditions on these timelike hypersurfaces. Our prescription is consistent with standard holographic results in the limit where the timelike hypersurface is taken to the conformal boundary.

The resulting stress tensor is proportional to the Brown-York stress tensor of the corresponding hypersurface plus certain boundary terms. These boundary terms are in principle uniquely defined when the hypersurfaces are taken to the asymptotic boundary and represent the necessary counterterms to ensure the on-shell action to be finite. On a finite cutoff the above-mentioned boundary terms cannot be fixed uniquely but we have shown that in

the hydrodynamic regime they only provide a redefinition of the thermodynamic quantities without affecting the thermodynamic relation or hydrodynamics.

Another source of boundary terms is the part of the spacetime between the finite cutoff and the boundary at infinity. In the spirit of Wilsonian holographic renormalization [34,35] (see also [36]), this part of the geometry is dual to the contribution of high energy degrees of freedom which can be integrated out, giving rise to a boundary effective action. In this paper we are taking a hard cutoff point of view along with e.g. [37,38]; namely we consider only the part of the geometry between the horizon and the cutoff itself, ignoring everything else beyond it. It would be interesting to see how in the hydrodynamic regime our results can be matched to the local contributions coming from the so-called UV part of spacetime.

Relative to earlier works (see for example [37,38]) we have clarified a number of subtleties. In particular, we have emphasized the fact that different coordinate systems give physically distinct fluids on timelike hypersurfaces obtained at any given radial cutoff. At leading order in the hydrodynamic expansions we can simply perform coordinate transformations and relate the pressures and energy densities but the hydrodynamic expansions are taken about different hypersurfaces and in particular with respect to different dual field theory spacetime coordinates; hence out of equilibrium we are dealing with physically different fluids. In the case of pure AdS gravity this subtlety does not arise with a flat or conformally flat Dirichlet boundary condition on the finite cutoff due to the fact that the conformal factor does not depend on the field theory coordinates but the issues discussed here would be relevant for dealing with hydrodynamics for cases such as AdS R-charged black holes (obtained as decoupling limits of rotating D3-branes).¹⁴

One of the conclusions of [37,38] was that the fluid changes from a relativistic to nonrelativistic fluid as the radial coordinate decreases. Here we found that the near horizon description is the Rindler fluid of [7,8], which indeed can be viewed as a nonrelativistic fluid.

After discussing classes of spacetimes with a general bulk stress tensor at thermodynamic equilibrium, we concentrated on the specific case of Einstein gravity in AdS and verified the consistency of our prescription for the fluid stress tensor with standard holographic results when the timelike hypersurface is taken to the conformal boundary of AdS. Having at our disposal the holographic dictionary at conformal infinity we gave a precise interpretation of the fluid on the cutoff hypersurface in terms of a specific deformation of the UV CFT. The resulting UV fluid can be thought of as living in a nonflat background, depending on the fluid velocity and temperature.

Finally, we have also explored the near horizon limit of the cutoff AdS fluid, which up to first order in a gradient expansion is effectively a Rindler fluid. We have emphasized the differences with the membrane fluid discussed earlier in the literature departing also from the interpretation of the membrane paradigm given in [38]. In particular we have showed how through the holographic-type construction one can obtain fluid equations up to arbitrary order in a gradient expansion in contrast to the membrane fluid which is only a suitable rewriting of certain components of Einstein equations into a fluidlike fashion. Of course one could easily use explicitly the form of the horizon metric and some derivative expansion of it in the membrane fluid equations, but this would be equivalent to taking the holographic point of view and would for example spoil the original structure of the membrane fluid equation.

Recently an interesting connection between asymptotically flat spacetimes and asymptotically AdS black holes has emerged [68,69]: it has been shown that asymptotically AdS black holes compactified on tori correspond to certain asymptotically flat Schwarzschild black branes and the holographic dictionary for the stress energy tensor has been derived through generalized dimensional reduction. It would be interesting to see how our construction would fit into this framework, and also how our construction can be applied to blackfolds [70,71] which interpolate between asymptotically AdS and asymptotically flat regions.

APPENDIX A: DETAILS OF THE HYDRODYNAMIC EXPANSION

The zeroth order metric is

$$ds^2 = -\frac{2}{\lambda} u_a dx^a dr + (G_{ab} - F u_a u_b) dx^a dx^b. \quad (\text{A1})$$

The inverse metric is

$$g^{(0)rr} = \lambda^2 F; \quad g^{(0)ra} = \lambda u^a; \quad g^{(0)ab} = \frac{h^{ab}}{G}. \quad (\text{A2})$$

¹⁴See the recent work [67].

The zeroth order Christoffel symbols are

$$\begin{aligned}\Gamma_{rr}^{(0)r} &= 0, & \Gamma_{rr}^{(0)a} &= 0, & \Gamma_{ra}^{(0)r} &= \frac{1}{2}\lambda F' u_a, \\ \Gamma_{ab}^{(0)r} &= -\frac{1}{2}\lambda^2 F(G'h_{ab} - F'u_a u_b), \\ \Gamma_{rb}^{(0)a} &= \frac{1}{2}\frac{G'}{G}h_b^a, & \Gamma_{ab}^{(0)c} &= -\frac{1}{2}\lambda u^c(G'h_{ab} - F'u_a u_b),\end{aligned}\quad (\text{A3})$$

with useful contractions being

$$\Gamma_{\mu r}^{(0)\mu} = \frac{1}{G^{d/2}}\partial_r G^{d/2}; \quad \Gamma_{\mu a}^{(0)\mu} = 0. \quad (\text{A4})$$

After promoting the parameters to depend on x , the metric (A1) is not a solution of the Einstein's equations. However adding corrections $g^{(n)}$ one can construct a solution order by order. The usual gauge choice is $g_{rr}^{(n)} = g_{ra}^{(n)} = 0$ so that the lines at constant x^a are bulk radial null geodesics and the metric keeps the Eddington-Finkelstein form to all orders, which is useful in order to avoid coordinate singularities at the horizon.

The variations of the Christoffel symbols can be computed formally to all orders using

$$\delta\Gamma_{\mu\nu}^{(n)\rho} = \frac{1}{2}g^{(0)\rho\lambda}(\bar{\nabla}_\mu g_{\lambda\nu}^{(n)} + \bar{\nabla}_\nu g_{\lambda\mu}^{(n)} - \bar{\nabla}_\lambda g_{\mu\nu}^{(n)}), \quad (\text{A5})$$

where $\bar{\nabla}_\mu$ is the covariant derivative with respect to the background zeroth order metric. Hence using (A3) we can compute

$$\begin{aligned}\delta\Gamma_{rr}^{(n)\mu} &= 0, \\ \delta\Gamma_{ra}^{(n)r} &= \frac{1}{2}\lambda u^c \partial_r g_{ca}^{(n)} - \frac{1}{2}\lambda \frac{G'}{G} u^c h_a^d g_{cd}^{(n)}, \\ \delta\Gamma_{ab}^{(n)r} &= -\frac{1}{2}\lambda^2 F \partial_r g_{ab}^{(n)} + \frac{1}{2}\lambda^2 (G'h_{ab} - F'u_a u_b) u^c u^d g_{cd}^{(n)}, \\ \delta\Gamma_{rb}^{(n)a} &= \frac{1}{2}\frac{1}{G} h^{ac} \partial_r g_{cb}^{(n)} - \frac{1}{2}\frac{G'}{G^2} h^{ac} h_b^d g_{cd}^{(n)}, \\ \delta\Gamma_{ab}^{(n)c} &= -\frac{1}{2}\lambda u^c \partial_r g_{ab}^{(n)} + \frac{1}{2}\frac{\lambda}{G} (G'h_{ab} - F'u_a u_b) h^{ce} u^f g_{ef}^{(n)},\end{aligned}\quad (\text{A6})$$

and the useful contractions

$$\delta\Gamma_{\rho r}^{(n)\rho} = \frac{1}{2}\partial_r \left(\frac{1}{G} h^{cd} g_{cd}^{(n)} \right); \quad \delta\Gamma_{\rho a}^{(n)\rho} = 0. \quad (\text{A7})$$

The variations of the Ricci tensor to all orders can be computed using

$$\delta R_{\mu\nu}^{(n)} = -\bar{\nabla}_\mu \delta\Gamma_{\rho\nu}^{(n)\rho} + \bar{\nabla}_\rho \delta\Gamma_{\mu\nu}^{(n)\rho}, \quad (\text{A8})$$

which gives (147).

The Christoffel symbols up to first order obtained from the seed metric (A1) with parameters depending on x are

$$\begin{aligned}\Gamma_{rr}^{(1)\mu} &= 0, \\ \Gamma_{ra}^{(1)r} &= \frac{1}{2}\lambda u_a F' + \frac{1}{2}a_a - \frac{1}{2}D_a^\perp \ln \lambda, \\ \Gamma_{ab}^{(1)r} &= -\frac{1}{2}\lambda^2 F(G'h_{ab} - F'u_a u_b) - \lambda K_{ab} G + u_{(a} a_{b)} \lambda F \\ &\quad + u_{(a} \lambda D_{b)}^\perp F - \frac{1}{2}\lambda u_a u_b D F + \\ &\quad - \frac{1}{2}\lambda h_{ab} D G + \lambda F u_{(a} \partial_{b)} \ln \lambda, \\ \Gamma_{rb}^{(1)a} &= \frac{G'}{2G} h_b^a + \frac{1}{G\lambda} \Omega_b^a + \frac{1}{2G\lambda} a^a u_b - \frac{1}{2\lambda G} u_b D^\perp \ln \lambda, \\ \Gamma_{ab}^{(1)c} &= -u^c K_{ab} + u^c u_{(a} a_{b)} - \frac{1}{2}\lambda u^c (G'h_{ab} - F'u_a u_b) + \\ &\quad - \frac{(G-F)}{G} (2u_{(a} \Omega_{b)}^c + a^c u_a u_b) + \frac{1}{G} h_{(a}^c \partial_{b)} G + \\ &\quad - \frac{1}{2G} h_{ab} D^\perp G + \frac{1}{2G} u_a u_b D^\perp F + u^c u_{(a} \partial_{b)} \ln \lambda,\end{aligned}\quad (\text{A9})$$

and useful contractions

$$\begin{aligned}\Gamma_{\rho r}^{(1)\rho} &= \frac{1}{G^{d/2}} \partial_r G^{d/2}; \\ \Gamma_{\rho a}^{(1)\rho} &= \frac{1}{G^{d/2}} \partial_a G^{d/2} + u_a D \ln \lambda - D_a^\perp \ln \lambda.\end{aligned}\quad (\text{A10})$$

The Ricci tensor components are shown in (181).

The general solution to Eqs. (196)–(199) is

$$\begin{aligned}\gamma^{(1)} &= (\gamma_0 r + \gamma_1 r^2) \theta, \\ \beta_a^{(1)} &= r \left(\beta_0 r + \frac{\beta_1}{r^d} - \frac{L}{r_c \sqrt{h_c}} \delta(r_c) \right) a_a, \\ \alpha^{(1)} &= \frac{\alpha_0}{r^{d-1}} \theta + \frac{L}{d h_c^{3/2}} \frac{r}{r_c} ((d-1)(h-1) + 2(h_c-1)) \theta, \\ \tilde{\gamma}_{ab}^{(1)} &= \frac{1}{2} \frac{L \sqrt{h_c}}{r_c r_H} r^2 (4k(r) + \tilde{\gamma}_0 + \tilde{\gamma}_1 \ln h(r)) \sigma_{ab},\end{aligned}\quad (\text{A11})$$

where $k(r)$ is given by (206) and $\gamma_0, \gamma_1, \beta_0, \beta_1, \alpha_0, \tilde{\gamma}_0$ and $\tilde{\gamma}_1$ are integration constants. Dirichlet boundary conditions fix some of them to

$$\begin{aligned}
\gamma_1 &= -\frac{\gamma_0}{r_c}, \\
\beta_1 &= r_c^d \left(-r_c \beta_0 + \frac{L}{r_c \sqrt{h_c}} \delta(r_c) \right), \\
\alpha_0 &= -\frac{(d+1)}{d} \frac{L r_c^{d-1}}{h_c^{3/2}} (h_c - 1), \\
\tilde{\gamma}_0 &= -4k(r_c) - \tilde{\gamma}_1 \ln h_c,
\end{aligned} \tag{A12}$$

Landau gauge conditions (200)–(201) fix the other integration constants to

$$\begin{aligned}
\gamma_0 &= \frac{2L}{r_c \sqrt{h_c}}, \\
\beta_0 &= -\frac{L(dh_c(2+(d-1)\delta(r_c)) - (d+1)(2+d\delta(r_c)))}{2(d+1)r_c^2 h_c^{3/2}} \delta(r_c),
\end{aligned} \tag{A13}$$

and requiring regularity on the horizon r_H gives

$$\tilde{\gamma}_1 = \frac{4}{d+1}, \tag{A14}$$

leading to the solutions (202)–(205).

APPENDIX B: DETAILS ON THE 2 + 1 + 1 FOLIATION OF THE SPACETIME

Knowing (258), (259) and (260) it is possible to show the following identities:

$$\mathcal{D}_\alpha B = 0; \quad \mathcal{D}_\alpha (C/A) = 0 \quad \text{on } \mathcal{H}. \tag{B1}$$

These can then be used to derive the useful relations

$$q_\alpha^\nu \nabla_k l_\nu = -\Omega_\alpha^{(l)} + \mathcal{D}_\alpha \ln A; \quad q_\alpha^\nu \nabla_l k_\nu = \Omega_\alpha^{(l)}. \tag{B2}$$

Let us first consider

$$\begin{aligned}
&(\nabla_\beta \nabla_\alpha - \nabla_\alpha \nabla_\beta) m^\beta \\
&= \nabla_\beta \Theta_\alpha^{(m)\beta} + h^\beta \nabla_\beta \Omega_\alpha^{(l)} + \Omega_\alpha^{(l)} \theta^{(h)} + \Omega_\alpha^{(l)} \nu_{(l)} + \\
&\quad - C \nu_{(k)} \Omega_\alpha^{(l)} + \Theta_\alpha^{(h)\beta} \Omega_\beta^{(l)} - \Theta_\alpha^{(l)\beta} \mathcal{D}_\beta \ln A \\
&\quad + m_\alpha \Omega^{(l)\beta} \Omega_\beta^{(l)} - l_\alpha \Omega^{(l)\beta} \mathcal{D}_\beta \ln A - l_\alpha \nabla_\beta (\nabla_k l^\beta) \\
&\quad + m_\alpha \nu_{(l)} \nu_{(k)} - k_\alpha \mathcal{L}_l \nu_{(l)} - \nu_{(l)} \nabla_l k_\alpha - \nu_{(l)}^2 k_\alpha + \\
&\quad - \nu_{(l)} k_\alpha \theta^{(l)} + (\theta^{(k)} + \nu_{(k)}) \nabla_\alpha C - C k_\alpha \nabla_\beta (\nabla_l k^\beta) + \\
&\quad - \nu_{(k)} l_\alpha \mathcal{L}_k C - C l_\alpha \mathcal{L}_k \nu_{(k)} - C \nu_{(k)} \nabla_k l_\alpha - C \nu_{(k)}^2 l_\alpha + \\
&\quad - C \nu_{(k)} \theta^{(k)} l_\alpha - \nabla_\alpha \theta^{(m)} - \nabla_\alpha (\nu_{(l)} + C \nu_{(k)}) + \\
&\quad - \Theta_\alpha^{(k)\beta} \mathcal{D}_\beta C + \nu_{(k)} l_\alpha \nabla_k C,
\end{aligned} \tag{B3}$$

where we repeatedly used (274). By further projecting on q , using (B2)–(B1) and the relations

$$q_\alpha^\nu \nabla_\mu \Theta_\nu^{(m)\mu} = \mathcal{D}_\mu \Theta_\alpha^{(m)\mu} + \Theta_\alpha^{(m)\mu} \mathcal{D}_\mu \ln A, \tag{B4}$$

$$q_\alpha^\nu \mathcal{L}_h \Omega_\nu^{(l)} = q_\alpha^\nu h^\mu \nabla_\mu \Omega_\nu^{(l)} + \Theta_\alpha^{(h)\mu} \Omega_\mu^{(l)}, \tag{B5}$$

as well as Einstein equations (278) we get the generalized Damour-Navier-Stokes equation (279). Equations (280)–(281) can be derived similarly.

To derive Eq. (282) we consider

$$h^\rho \nabla_\rho \nabla_\mu m_\nu q_\alpha^\mu q_\beta^\nu = h^\rho (R_{\nu\sigma\rho\mu} m^\sigma + \nabla_\mu \nabla_\rho m_\nu) q_\alpha^\mu q_\beta^\nu, \tag{B6}$$

and repeatedly make use of (274)–(275), (B2) and

$$q_\alpha^\mu q_\beta^\nu \mathcal{L}_h \Theta_{\mu\nu}^{(m)} = q_\alpha^\mu q_\beta^\nu \nabla_h \Theta_{\mu\nu}^{(m)} + \Theta_{\alpha\rho}^{(m)} \Theta_\beta^{(h)\rho} + \Theta_{\beta\rho}^{(m)} \Theta_\alpha^{(h)\rho}. \tag{B7}$$
