CHAPTER 10

DATA RESEARCH ON CHILD ABUSE AND NEGLECT WITHOUT INFORMED CONSENT? THE DUTCH APPROACH

Eva M.M. Hoytema van Konijnenburg
Arianne H. Teeuw
M. Corrette Ploem
ABSTRACT

According to the Declaration of Helsinki, participation of human subjects in medical research is only acceptable if subjects have given their consent. But in child abuse and neglect, many studies use a design in which subjects do not actively participate. Data in these studies are gathered from sources such as medical records or Child Protective Services. As long as such data are used anonymously, this does not interfere with individual privacy rights. However, some research is only possible when carried out with personally identifiable data, which could potentially be misused. In this paper, we discuss in which situations and under which conditions personal data of children may be used for a study without obtaining consent. In doing so, we make use of two recent studies, performed in our hospital, in which we encountered this issue. Both studies involved collecting personal data. After careful consideration, we decided not to ask informed consent; instead, we arranged for specific safeguards to protect the subject’s and their parents’ privacy as well as possible. Altogether, we conclude that our approach fits within the Dutch legal framework and seems a reasonable solution in situations in which individual privacy rights are at odds with the public interest of child abuse and neglect research. We argue that, although, in principle, data research is only acceptable after informed consent is obtained, the law should allow that, under specific circumstances and safeguards, this requirement is put aside to make research in the field of child abuse and neglect possible.
INTRODUCTION

According to the Declaration of Helsinki, participation of human subjects in medical research is only acceptable if subjects (or their legal representatives – e.g. parents) are fully informed of all aspects of the study and have given their consent. However, in the field of child abuse and neglect, many studies use a design in which subjects do not actively participate. Such studies make use of available data about the children, their parents and applied (health care) services and interventions to reduce child abuse and neglect. These data are gathered from sources such as medical records, records of Child Protective Services and data provided by community services. As long as such data are used anonymously, this does not interfere with individual privacy rights of the involved research subjects (which could be both the child and his or her parents). But in some situations, the use of anonymous data does not suffice, e.g. because the data needs deduplication or linking to data from other sources. In these situations, it is necessary to use personally identifiable (or personal) data, meaning that it is reasonably possible to trace an individual’s identity from the data (i.e. without a disproportionate use of means available to identify the person to whom the information relates). The use of such data could potentially cause problems or harm to the subjects or their parents when it is misused or ends up in wrong hands.

In research that is carried out in our hospital, we aim at linking data from different sources (medical records, records of Child Protective Services and community services, and self-reported data). This is only possible by using personal data. Whereas we know that, in principle, all subjects should provide informed consent before their data is used, we experience that this is often not feasible e.g. because the child and his or her parents are not traceable, or – in case of large-scale database studies – it lacks means and time to approach each individual subject. Another problem is that in child abuse research, asking for informed consent may lead to a serious non-response bias. In this paper, we discuss in which situations and under which conditions a research project could be performed without obtaining consent.
informed consent of the research subjects. In doing so, we refer to two recent studies in our hospital in which we encountered these issues.

**DATA RESEARCH: TWO EXAMPLES**

**Example 1: evaluation of a protocol to identify child abuse and neglect**

We conducted a study to evaluate a recently implemented hospital-based guidance protocol to improve identification of abused or neglected children in hospitals. This new protocol was based on a protocol developed in The Hague, The Netherlands in 2007. In the new protocol, all adults presenting at the emergency department because of medical problems due to intimate partner violence, substance abuse or a suicide attempt are asked whether they care for children under 18 years of age. If so, children and their parents are referred to the outpatient pediatric department for an examination. After this visit, referrals to services can be arranged. If parents refuse to cooperate after several reminders, children are reported to the Child Abuse Counseling and Reporting Centre (in Dutch: Advies en Meldpunt Kindermishandeling, AMK). If necessary, the AMK can decide to hand over serious cases to the Child Care and Protection Board (in Dutch Raad voor de Kinderbescherming, RvdK), which is a division of the Ministry of Security and Justice. To evaluate this protocol, we used several outcome measures. First, we used parent- and child-reported outcomes, for which we asked informed consent. However, based on previous studies and the opinion of other authors, we expected a low participation rate. We were concerned that there would be a substantial non-response bias, that would severely limit the external validity of the results because we expected that eligible subjects who were unwilling to participate in the study suffered from more problems than subjects who were willing to participate. In order to collect results from an unselected group, we wanted to include reports of hospital staff, AMK records and RvdK records of all eligible subjects in the study (thus without asking for informed consent). Therefore, we would need to search AMK and RvdK records, and we needed to ask information.
from hospital staff. For all this, we could not use anonymous data, because we wanted to link data from different sources and, because the study was conducted in multiple hospitals, deduplicate (hospital staff could be unaware if subjects visited multiple hospitals during the study period). After discussing our dilemma in a multidisciplinary team (including a hospital lawyer specialized in privacy matters, a dedicated hospital privacy officer and a pediatrician specialized in child abuse and neglect) we used the following protocol in handling personal data: one researcher collected all data from hospital staff. We asked the staff to make a notification about participation in our study in the subjects' records. If subjects would raise an objection against the use of their personal information in research, all information would be destroyed immediately. In the context of our approach, we could not inform subjects individually about our study, but in the majority of the participating hospitals, the general hospital leaflets contains a statement that, without objection, personal medical information can be used for research and patients will never be identifiable in any publications. There are instructions on how to object to this. After the data were collected, the main researcher (after signing a confidentiality agreement) searched for 'hits' in the AMK and RvdK records. During the study, all personal information was coded and a key list was only kept by a trusted third party (a senior researcher, who was experienced in the field but not involved in this study). As soon as all data analyses were finished, all personal information were destroyed carefully.

Example 2: validation of a screening test for child abuse and neglect
We conducted a study that aimed to validate two (already implemented) screening tests to identify child abuse and neglect at the hospital emergency department: a checklist called SPUTOVAMO, and a complete physical inspection. All children visiting the emergency department underwent screening and were included in the study. As a reference standard, a multidisciplinary child protection team evaluated children with a positive screening result on either of the tests, and assessed the presence of (a suspicion of) child abuse and neglect. This was all part of usual clinical care,
data were used anonymously and children and parents were not asked to provide informed consent. As a next step however, we wanted to evaluate the proportion of false negative test results (children with negative results on both screening tests who were in reality victims of child abuse and neglect). For these children, and for children who had a positive screening test but were not evaluated by the multidisciplinary child protection team (missed diagnosis), we wanted to use AMK reports as a proxy reference standard for a child abuse diagnosis. Therefore, we needed to search the AMK database, which is not part of usual care and would require the use of personal identifiable data. After consideration, we did not want to ask informed consent for the AMK database search because, as with the previous study, we were concerned that parents who were maltreating their children, or who had been in contact with the AMK or other youth care organizations in the past, would be less inclined to participate in the study. This would result in an overestimation of the sensitivity of the screening tests, with potentially dangerous consequences for future, maltreated children. Again, after discussing the study in the same multidisciplinary team as mentioned in example 1, we used the following protocol: only the main researcher (after signing a confidentiality agreement) searched for ‘hits’ in the AMK records. In this hospital, the general leaflet includes a statement that, without objection, personal information can be used in medical research. If patients would raise an objection against the use of their personal information in the study, all information would be destroyed immediately. During the study, all personal information was coded and a key list was only kept by a trusted third party (the head of the pediatric department, who was not involved in the study). As soon as all data analyses were finished, all personal information were destroyed carefully.

**LEGAL FRAMEWORK FOR DATA RESEARCH**

**European level**

When medical data research is involved, the main rules are provided by binding legislation (‘hard law’) of the European Union (EU). We refer at
a directive, adopted in 1995, on the protection of individuals with regard to the processing of personal data and on the free movement of such data (Directive 95/46/EC) 16. By now, all EU-Member States incorporated the directive’s provisions into their national laws. Although its framework on handling personal data of a particular sensitive nature, which medical data clearly are, is strict, it takes into account the importance of data processing for scientific research (in the medical field). It allows that the rights of individual ‘data subjects’ (e.g. patients) are restricted when data processing for important research purposes is involved. The directive offers no more than a general legal framework. In this area, non-binding ('soft law') rules and principles, developed by e.g. the Council of Europe and the European Science Foundation, provide further guidance. The main principle embodied in these (binding and non-binding) documents, is that medical data which are not anonymous, but (directly or indirectly) identifiable, may be collected and used for a research project if the data subject or his/her legal representative has given informed consent. However, when – despite reasonable efforts – it would be impracticable to seek the individual’s consent, the data may be gathered without the individual’s explicit consent, provided that certain conditions are met. One of these conditions is that the data subject knows about the possible use of his or her data for scientific research (right to be informed on a general level) and has not objected to this (right to ‘opt-out’) 17.

Presently, the European Union is in the middle of reforming the data protection framework. It is developing the so-called ‘General Data Protection Regulation’, which is not only binding to the EU-Member States (as the Directive), but also directly applicable in the Member States, making implementation unnecessary. Because the draft Regulation, once adopted, may leave less room for research with medical data than the present EU-framework, i.e. by providing stricter conditions for research in situations in which it would be impracticable to seek the individual’s consent, it is subject to strong debate in and outside the medical research community 18 19 20. The regulation’s adoption is not expected before the end of 2015.
National level
In The Netherlands, in the context of medical data research, two laws are relevant: the Personal Data Protection Act (in Dutch: ‘Wet bescherming persoonsgegevens’) and the Medical Contract Act (in Dutch: Wet inzake de geneeskundige behandelingsovereenkomst), a section of the Dutch Civil Code. Here, we pay only attention to the latter because that is the one that provides specific rules for disclosing patient data for medical research. On the basis of Article 7:457 Civil Code, a physician or caregiver may disclose identifiable patient data to researchers when the patient authorized the disclosure. However, when obtaining consent appears to be impossible or would involve a disproportionate effort, that requirement may be dropped under the following conditions. First, the research project should serve a public interest; second, the research could not be carried out without the data concerned; third, the data subject is informed about the possible use of his/her data for research and has not explicitly opposed to this; and fourth, adequate security measures (technical and organizational) are taken (e.g. encoding the data).

We would like to note that, whereas this framework fits within the present EU-directive, it might come in conflict with the future EU-regulation.

DISCUSSION
In child abuse and neglect research, studies using linkable data of unselected samples are often necessary to yield unbiased results of sufficient quality. Since the results of these studies can have important consequences for the social, mental and medical well-being of maltreated children and their families, we argue that, in very specific circumstances, it should be possible to perform such research without informed consent of the child and/or the parents involved. In this paper, we presented two examples: the first evaluating a new protocol implemented to identify child abuse and neglect by assessing high risk parents; and the second evaluating the diagnostic accuracy of two screening tools for maltreatment used in children at the
emergency department. The most important reason not to ask informed consent was that we expected a severe non-response bias if we would only include families who were willing to participate. In both studies, the screening methods to identify child abuse and neglect that we wanted to investigate were already implemented in clinical care, although they had never been evaluated. We believe that good quality evaluation research is very important. However, in carrying out such research, the protection of privacy of research subjects may not, or at least as minimal as possible, be compromised. And for researchers also very important: the performance of the study may not come into conflict with legal standards. According to Dutch law (Medical Contract Act; see before), consent can only be dropped if the research project serves a public interest, the project could not be carried out without the requested data and the stored data are well secured by encoding them. And last but not least: the data subject is informed about the possible use of his/her data for research and has not explicitly opposed to this. With our approach, we were able to fulfill those conditions: the studies serve a public interest and could not be carried out without the data involved. As illustrated by the two examples as described before, we took several safeguards to ensure that the privacy of research subjects was protected as much as possible. First, we used an approach in which only the main researcher had access to personal data and no information was handed over to other parties (such as the AMK). This way, the other parties could never use any information from the study in a way that could potentially negatively affect research subjects. If we would have asked the AMK to look for hits of our study participants in their databases, AMK staff could have used this information in their clinical assessments, which could have had consequences for the study subjects. The downside of having the researcher searching in databases of other parties is that the researcher could look up extra, non-relevant, information of study subjects or other persons, thus violating the privacy of these persons. Other than signing a confidentiality agreement, we could not be 100% sure that this would not happen. Another safeguard was immediate coding of personal information, meaning that – by making use of a trusted third party (based in a different department of
our institution) – all personal data were stored separately from the research data. By doing so, although not completely avoided, the risk that meaningful personal information would end up in wrong hands was minimal. We would like to note, however, that if financially feasible, it would be preferable, to use a completely independent trusted third party as a linkage center. This way, personal data are coded at the linkage center before any other information is retrieved from parties and send to researchers. Furthermore, research subjects and/or their representatives were informed about the possibility that their data could be used for medical research in general by a statement in the hospital leaflet or on the hospital website.

**FINAL REMARKS**

In this paper, we discussed an approach to conduct research about child abuse and neglect without obtaining informed consent. This approach is consistent with the Dutch legal framework (therefore: the Dutch approach), and may be valuable for other countries. However we argue that some improvements should be made.

First, we only partly fulfilled the ‘opt-out’ condition for research subjects, because, although in theory patients could read a statement about research based on patient records and instructions to object, most patients were probably not aware of this. We therefore recommend an improved opt-out procedure in the sense that it is better secured that patients and/or their legal representatives are really aware of the fact that their medical records could be used in research, and that they are always entitled to object to such use. Hospitals could develop special leaflets for using medical data for research and put these posters or leaflets in waiting rooms, and the information could be put prominent on their websites. To prevent that patients opt out without even considering their participation, it should be clearly explained that the research is used to improve medical care, that personal information will never be distributed or published, and that patients will not experience any negative consequences.

Second, when researchers refrain from obtaining informed consent while
they make use of personal data, we recommend a review of the research proposal by a Medical Ethics Committee or comparable body, especially in sensitive research areas as on child abuse and neglect. Although this is not a current requirement under Dutch law, it is recommended by non-binding documents such as the Council of Europe’s Recommendation No. R (97) 5 on the Protection of Medical Data (Feb. 13, 1997) \textsuperscript{22}; (see Article 12.2 sub c).

We would like to conclude that our ‘Dutch approach’ seems a reasonable solution in situations in which individual privacy rights are at odds with the public interest of child abuse and neglect research. We argue that, – although, in principle, medical research with human subjects is only acceptable after informed consent is obtained – the law should allow that under certain circumstances and safeguards the informed consent requirement is put aside to avoid that research in the field of child abuse will be(come) impossible.
