Graphical abstract

Schematic depiction of the initial stages of the neurogenic cascade in control animals (left) or aged animals (right). Phenotypical alterations are: increased quiescence and decreased proliferation. In this chapter we discuss that glucocorticoid receptor expression in neural precursor cells is associated with different age-related decay kinetics.
Abstract

Aging is associated with alterations in neuro-endocrine functions, including a dysregulation of the hypothalamo-pituitary-adrenal (HPA) axis and glucocorticoid levels. This dysregulation coincides with cognitive impairments and an overall decrease in hippocampal neural precursor cell (NPC) proliferation. NPC sensitivity to glucocorticoids has been found to change with age, with a significant increase in glucocorticoid receptor (GR) expression present in the quiescent and activated neural stem/progenitor cell populations, known as type-1 and type-2 cells. So far, a more detailed characterization of the GR in NPC populations and their dynamics with age is lacking.

Here, we used Nestin-GFP mice to characterize age-related changes in specific NPC populations, and investigated their relationship with GR (co-)expression in hippocampi of 3 age groups: young, young adult and middle-aged mice. We used linear and non-linear models to characterize the relative decay of the type-1 and type-2 NPC subsets. Our results demonstrate that the presence or absence of GR expression identifies different NPC populations. We found that type-1 and type-2 NPCs expressing the GR followed linear age-related decay kinetics, whereas type-1 and type-2 NPCs lacking GR followed non-linear decay kinetics. Interestingly, although NPCs lacking GR expression were readily identified at young ages, NPC populations lacking GR expression were rare in young adult and middle-aged mice, suggesting either an age-dependent GR upregulation in NPCs or alternatively, a higher age dependent decline of this subpopulation. Although all NPC populations decreased in number with age, populations expressing GR typically displayed slower decay kinetics, suggesting a role for the GR in NPC population maintenance during aging.
Age-related NPC decay kinetics are associated with GR expression

Chapter 6

Introduction

Following exposure to stress, the HPA axis is activated, releasing several hormones that mediate the stress response. Among these, glucocorticoid hormones (CORT) are powerful mediators released from the adrenal cortex following circadian as well as ultradian rhythms. These pulsatile release patterns are affected by stressors such as sleep deprivation, chronic psychological stress, and age. In particular, a reduction in the amplitude of the circadian CORT rhythm has been associated with aging, largely resulting from elevations in evening CORT levels and decreases in diurnal CORT. This altered endocrine profile correlates with a decline in hippocampus-related cognition. The hippocampus contains NPCs that continue to form new neurons throughout adulthood. This process of 'adult hippocampal neurogenesis' (AHN) has been implicated in hippocampus-related cognition, including spatial memory, HPA axis regulation, and shows a marked age-associated decline, particularly in the proliferation and differentiation capacity of the hippocampal NPCs.

Materials and methods

Animals, immunohistochemistry and confocal microscopy.

Male 1, 3, 6 and 10 month old Nestin-GFP transgenic mice (n=3 per group) were used for immunocytochemistry. Mice were single housed under standard laboratory cage conditions and kept under 12 hour light/dark cycles with ad libitum access to food and water. At the indicated ages, animals were transcardially perfused with 4% paraformaldehyde in PBS and brains were extracted, sectioned in 8 series of 40µm and immunostained as described before, using the following antibodies: polyclonal chicken anti-GFP (Abcam. 1:500), monoclonal mouse anti-GFAP (Chemicon. 1:1000) and polyclonal rabbit anti-GR (H300 Santa Cruz. 1:100) in combination with goat anti-chicken Alexa488 (Invitrogen. 1:500), goat anti-mouse Alexa647 (Invitrogen. 1:500) and goat anti-rabbit Alexa568 (Invitrogen. 1:500), respectively. Sections were counterstained for DNA using Hoechst (Invitrogen. 1:20000) to detect cell nuclei. Confocal microscopy was performed as described before using a Zeiss LSM510 laser scanning microscope.
performed only on the adult age groups (3, 6 and 10 months) as described before and were either expressed in absolute numbers per hippocampus or in relative percentages of total NPC subpopulation.

**Generation of best-fit curves and statistical analysis.**

Second order polynomial best-fit curves \((y(x) = ax^2 + bx + c)\) including their 95% confidence intervals were based on the absolute numbers of GR+ and GR- type-1 and type-2 adult NPCs per hippocampus derived from 3, 6 and 10 month old Nestin-GFP transgenic mice, using Graphpad Prism 5.0 software. Second order polynomial best fit curves were statistically compared to a first order polynomial curve fitting \((y(x) = ax + b)\) using an extra-sum-of-squares F-test and they were considered significantly different if the extra-sum-of-squares F-test reached a \(p < 0.05\). Subsequently, curve parameters such as increment and slope from GR+ and GR- type-1 and type-2 NPC were compared using an extra-sum-of-squares F-test. The calculated parameters were considered significantly different when the extra-sum-of-squares F-test reached a \(p < 0.05\). All other comparisons were statistically tested using one-way analysis of variance (ANOVA) test with a Tukey’s post-hoc test. Graphpad Prism 5 software was used for the generation of best-fit curves and statistical analysis.

**Results**

Nestin-GFP, GFAP and GR immunoreactivity was readily detectible in the subgranular zone (SGZ) of the dentate gyrus of animals from 1 month up to 10 months of age (Figure 1A-D). Based on the expression of these 3 markers, NPC were classified in different subtypes, using a previously described system of developmental milestones. Based on their GFAP (co-)expression, type-2 NPCs can be further separated into type-2a (Nestin-GFP+/GFAP+) and type-2b (Nestin-GFP+/GFAP-) NPCs. In the brains of adult animals (i.e. 3 months or older), the type-1, -2a and -2b NPCs could be clearly identified (Figure 2A-F). In contrast to previous observations, we observed a significant age-related decrease in the type-1 cells numbers between young adult, mature adult and middle-aged mice (p < 0.01) (Figure 1E). The same applied to the type-2a cell numbers (Figure 1E). Importantly, a more marked age-related decrease was found in type-2b cell numbers (Figure 1E), that were the largest NPC population in young adult animals and became the smallest population in mature adult and middle-aged mice (Figure 1E).

As the GR is an important regulator of NPCs, differential GR expression in NPC subpopulations could provide a possible explanation for the differential sensitivity to GCs. To test this, we characterized GR expression in type-1 and type-2 cells of the three adult age groups included in this study and observed a significant age-related decay in the relative abundances of GR+ type-1, type-2a and type-2b cells (Figure 2G). We observed that 86.8±3.7% of type-1 cells and 71.6±9.3% of type-2a cells were GR+ in Nestin-GFP transgenic mice at 3 months of age (Figure 2G). Notably, we found that 31.3±8.5% of type-2b cells were GR+ (Figure 2G).

We next characterized age-related patterns in the expression of GR+ and GR- type-1 and type-2 cell numbers using linear and non-linear models of cell-population dynamics. We tested whether GR+ and GR- type-1 and type-2 cell numbers fitted better to a first order polynomial equation (linear dynamics model), or to a second order polynomial equation (non-linear dynamics model) (Figure 3A-F and Tables 1-3). Interestingly, the cell population decay of GR+ type-1 (Figure 3A; Table 1), type-2a (Figure 3C; Table 2) and type-2b (Figure 3E; Table 3) cells fitted best to a linear dynamics model, while the cell population decay of type-1/GR- (Figure 3B; Table 1) and type-2b/GR- (Figure 3F; Table 3) cells showed fitted best to a non-linear dynamics model. GR-Type-2a cells, however, fitted best to a linear dynamics model (Figure 3H, Table 4).

Next, we directly assessed whether GR expression significantly affected age-related population dynamics in type-1, type-2a and type-2b NPC populations (Figure 3G-I and Table 4). To this aim, for type-1 and type-2b cells we compared specific non-linear dynamics model curve parameters between GR+ and GR- subsets (Figure 3G and 3I, Table 4) and for type-2a we compared specific linear dynamics model curve parameters between GR+ and GR- subsets (Figure 3H, Table 4). The parameters used for comparison included increment (initial number of cells) and slope (decay kinetics of NPC). The curve fit corresponding to

Age-related NPC decay kinetics are associated with GR expression

**Discussion**

The aim of this study was to characterize NPC population sensitivity to age-related decline in numbers and whether this could be coupled to GR expression levels. NPC population dynamics can be considered a multidimensional system with numbers being influenced by NPC quiescence, (asymmetric and symmetric) division, differentiation and apoptosis. Accordingly, we first analyzed which mathematical functions fitted best to the different NPC subpopulations. Exponential functions were discarded since they did not fit well and had a very large 95% confidence interval. This uncertainty is due to a transition period between postnatal and adult neurogenesis in which NPC populations were not quantified. Quadratic and linear functions, however, fitted the data well, with good 95% confidence intervals.

Our observations confirmed that type-1 and type-2 NPCs decline selectively with age as demonstrated before, and show for the first time that this decline is associated with expression of the GR. These observations suggest that NPCs have differential age-related sensitivities to systemic factors, such as GC. Furthermore subsets of NPCs that co-express GR in the young adult hippocampus are well preserved with age, consistent with their dominance also found in middle-age mice. In addition, NPC subsets expressing the GR tended to follow age-related decay with a less drastic, linear, kinetic pattern as compared to those lacking GR expression.

Data point values (polygons) are expressed as mean±SEM of three animals. Best-fit curve values (lines) are expressed as mean±95% confidence interval. (G-I) Best-fit curves were compared for significant differences (###p < 0.001) between GR+/GR- NPC subsets using sum of squares F-test within the 3-10 months domain.
GR expression, suggesting the GR may be involved in controlling age-related decay.

The age-related loss or deforestation of NPC has been proposed as a critical factor contributing to a decline in AHN with age\(^{29}\). The Nestin-GFP mice used in these studies represent a suitable model to study this decay. Importantly, potential difference in half-life time of Nestin versus GFP may not confound the interpretation of the relative abundance of GFP+/GFAP+ NPC populations in these transgenic mice\(^{15}\). Accordingly, in contrast to previous interpretations of GR expression patterns in NPC\(^{21}\) from our results it could be speculated that the GR is involved controlling age-related NPC decay under basal conditions. Consistent with this, retroviral-mediated knock-down of the GR in NPCs \textit{in vivo}, resulted in increased neurogenesis and accelerated NPC differentiation under basal stress-free conditions\(^{16}\). Therefore, our current and previous results combined suggest that GR expression may prevent NPC to prematurely undergo differentiation and thus indirectly favor an undifferentiated, proliferative phenotype. However, the specific mechanisms involved remain uncharacterized and are beyond the aim of this study. In agreement with our interpretation, lowering the enhanced CORT levels observed at old age (20-26 month-old rats) may release NPC from a CORT-induced quiescent state\(^{10}\). However, contrasting observations have been made when CORT levels were lowered from postnatal day 10 onwards\(^{31}\), emphasizing the age-dependent role of GC in the regulation of NPC.

It has been suggested that some aspects of the aging process are influenced by systemically secreted factors, which may inhibit AHN, including GC\(^{30}\). Attributed to a decreased amplitude but not maximum concentrations, basal daily rhythmicity of CORT secretion is one of the factors that has been described to flatten with age\(^{6,7}\), with a concomitant AHN decrease\(^{11}\). Although this ‘flattened CORT release’ phenotype cannot be further aggravated by e.g. increasing CORT levels\(^{32}\), adrenalectomy can restore the age dependent decrease in AHN\(^{30}\). A possible interpretation of this seemingly contradictory data can be two-fold, i.e. on the one hand, lowering CORT levels per se appears sufficient to enhance AHN, on the other, a loss of the pulsatile nature of basal CORT release could be involved in the regulation of AHN as well, providing a distinct signal controlling NPC proliferation (chapter 5).

While a number of previous studies have described general decreases in AHN with age\(^{12}\), a recent study has analyzed in more detail the age-related reduction of type-1 and type-2 NPCs specifically\(^{22}\). This was also based on the expression of Nestin-GFP and their respective radial or horizontal morphologies as in our current study. Interestingly, these authors found type-1 NPCs to gradually decrease whereas type-2 NPCs showed a more dramatic reduction between 6 and 9 months\(^{22}\), in agreement with our observations.

Additionally, other studies quantified age-related reductions in NPCs based on Notch signaling activity. Using Hes5::GFP reporter mice, Lugert et al. could identify both horizontal and radial NPC populations and found the levels of the former to decrease with increasing age and the levels of the latter to remain stable\(^{25}\). These differences regarding the age-dependent reduction in both subpopulations of NPCs, as compared with our observations, may arise from experimental differences including different antibodies used for the detection of cell-specific markers. Importantly, Lugert et al. examined NPC levels at different ages in heterogeneous groups of animals in

terms of age and sex of the animals, which is an important factor affecting AHN\(^2\) was not discriminated in this study\(^5\). Furthermore, it is unclear to what extent Hes5::GFP and Nestin-GFP expression overlap in the adult hippocampus, and thus whether they would identify exactly the same NPC populations. Interestingly, it has previously been demonstrated that Notch activity, as measured through Hes5 expression, promotes NPC self-renewal provided it follows an oscillatory nature, whereas sustained Notch activity induces differentiation\(^33\), indicating that quiescent NPCs, actively proliferating NPCs and differentiating newborn cells can all be Hes5+ or Hes5-\(^34\).

In theory, a decline in AHN can be achieved through changes in quiescence, proliferation, apoptosis and differentiation of type-1 and type-2 NPC subtypes. Our data show that GR- and GR+ type-2 NPC subsets harbor different age-related decay kinetics, with GR-/type-2a NPC preferentially following linear decay kinetics, while GR-/type-2b NPC followed non-linear decay kinetics. Interestingly, previous reports have described a differential apoptotic sensitivity between the type-1, 2a and 2b NPC, with the latter displaying the highest sensitivity to apoptosis\(^35\), possibly contributing to the non-linear decay kinetics of type-2b/GR- NPC.

Suggestively, we have previously described a link between active caspase-3 mediated NPC apoptosis and differentiation, that could be directed by GR activation\(^19\). Accordingly, it is possible that type-2b cell numbers are influenced by their relative levels of proliferation, apoptosis and differentiation, all of which can be regulated by the GR. This could explain the dramatic age-related decrease of type-2b/GR- NPC compared to type-2b/GR+ NPC.

Our observations are generally comparable to those made earlier by Garcia \textit{et al.} regarding the relative increases in NPCs (co-)expressing the GR with age\(^31\). In contrast though, we detected higher levels of type-1/GR+ NPCs at young age and found GR immunoreactivity in type-2b NPC, which could be due to differences in primary GR antibodies and in the Nestin-GFP transgenic strain used. Another likely scenario could be the sex differences between our study and those described by Garcia \textit{et al.}\(^31\) since e.g. sex hormones could underly gender specific expression of the GR in NPC. Indeed, a considerable body of evidence has highlighted the cross-talk between glucocorticoids and sex hormones through their respective receptors\(^36-38\) while previous reports describe both an age dependent increase in CORT levels yet a decrease in both male and female sex hormones\(^34\).

In conclusion, a role for the GR in disfavoring a proliferative phenotype in NPC with age could explain previous observations concerning differences in the relative age-related stability of NPC subsets. This suggests a GR-mediated protective effect on NPC decay or ‘deforestation’\(^29\) and/or quiescence/senescence\(^22,25,39\). Further analysis should address important questions arising from this hypothesis, such as to which extent this protective effect is mediated by alterations in symmetric vs. asymmetric NPC self-renewal, apoptosis or persistent quiescence.

Together, our data suggest that age-associated changes in HPA axis activity could contribute to the differential maintenance or decline of specific hippocampal NPC populations and thus to their neurogenic potential into older age.
