Mock modular Mathieu moonshine modules

Miranda C N Cheng1*, Xi Dong2, John F R Duncan3, Sarah Harrison2, Shamit Kachru2 and Timm Wrase2

Abstract
We construct super vertex operator algebras which lead to modules for moonshine relations connecting the four smaller sporadic simple Mathieu groups with distinguished mock modular forms. Starting with an orbifold of a free fermion theory, any subgroup of \( \text{Co}_0 \) that fixes a 3-dimensional subspace of its unique non-trivial 24-dimensional representation commutes with a certain \( \mathcal{N} = 4 \) superconformal algebra. Similarly, any subgroup of \( \text{Co}_0 \) that fixes a 2-dimensional subspace of the 24-dimensional representation commutes with a certain \( \mathcal{N} = 2 \) superconformal algebra. Through the decomposition of the corresponding twined partition functions into characters of the \( \mathcal{N} = 4 \) (resp. \( \mathcal{N} = 2 \)) superconformal algebra, we arrive at mock modular forms which coincide with the graded characters of an infinite-dimensional \( \mathbb{Z} \)-graded module for the corresponding group. The Mathieu groups are singled out amongst various other possibilities by the moonshine property: requiring the corresponding weak Jacobi forms to have certain asymptotic behaviour near cusps. Our constructions constitute the first examples of explicitly realized modules underlying moonshine phenomena relating mock modular forms to sporadic simple groups. Modules for other groups, including the sporadic groups of McLaughlin and Higman–Sims, are also discussed.

1 Introduction
The investigation of moonshine connecting modular objects, sporadic groups, and 2d conformal field theories has been revitalized in recent years by the discovery of several new classes of examples. While monstrous moonshine [3, 15, 21, 30, 36, 37, 44] remains the best understood and prototypical case, a new class of umbral moonshines tying mock modular forms to automorphism groups of Niemeier lattices has recently been uncovered [13, 14] (cf. also [6]). The best studied example, and the first to be discovered, involves the group \( M_{24} \) and was discovered through the study of the elliptic genus of K3 [35]. The twining functions have been constructed in [4, 31, 38, 39] and were proved to be the graded characters of an infinite-dimensional \( M_{24} \)-module in [43]. Steps towards a better and deeper understanding of this mock modular moonshine can be found in [7, 8, 18, 40–42, 46, 56, 57, 59–61], and particularly in [9], where the importance of K3 surface geometry for all cases of umbral moonshine is elucidated. Possible connections to space-time physics in string theory have been discussed in [5, 47–49, 63]. Evidence for a deep connection between monstrous and umbral moonshine has appeared in [25, 55].
In none of these cases, however, has a connection to an underlying conformal field theory\(^a\) (whose Hilbert space furnishes the underlying module) been established. The goal of this paper is to provide first examples of mock modular moonshine for sporadic simple groups \(G\), where the underlying \(G\)-module can be explicitly constructed in the state space of a simple and soluble conformal field theory.

Our starting point is the Conway module sketched in [36], studied in detail in [24], and revisited recently in [27]. The original construction was in terms of a supersymmetric theory of bosons on the \(E_8\) root lattice, but this has the drawback of obscuring the true symmetries of the model. In [24], a different formulation of the same theory, as a \(\mathbb{Z}_2\) orbifold of the theory of 24 free chiral fermions, was introduced. A priori, the theory has a \(\text{Spin}(24)\) symmetry. However, one can also view this theory as an \(\mathcal{N} = 1\) superconformal field theory. The choice of \(\mathcal{N} = 1\) structure breaks the \(\text{Spin}(24)\) symmetry to a subgroup. In [24] it was shown that the subgroup preserving the natural choice of \(\mathcal{N} = 1\) structure is precisely the Conway group \(\text{Co}_0\), a double cover of the sporadic group \(\text{Co}_1\).

In this paper, we show that generalizations of the basic strategy of [24, 27] can be used to construct a wide variety of new examples of mock modular moonshine. Instead of choosing an \(\mathcal{N} = 1\) superconformal structure, we choose larger extended chiral algebras \(\mathcal{A}\). The subgroup of \(\text{Spin}(24)\) that commutes with a given choice can be determined by simple geometric considerations; in the cases of interest to us, it will be a subgroup that preserves point-wise a 2-plane or a 3-plane in the 24 dimensional representation of \(\text{Co}_0\), or equivalently, a subgroup that acts trivially on two or three of the free fermions in some basis. In the rest of the paper, we will use \(\mathbf{24}\) to denote the unique non-trivial 24-dimensional representation of \(\text{Co}_0\), and use the term \(n\)-plane to refer to a \(n\)-dimensional subspace in \(\mathbf{24}\).

It is natural to ask about the role in moonshine, or geometry, of \(n\)-planes in \(\mathbf{24}\) for other values of \(n\). One of the inspirations for our analysis here is the recent result of Gaberdiel–Hohenegger–Volpato [40] which indicates the importance of 4-planes in \(\mathbf{24}\) for non-linear K3 sigma models. The relationship between their results and the \(\text{Co}_0\)-module considered here is studied in [25], where connections to umbral moonshine for various higher \(n\) are also established. We refer the reader to Sect. 9, or the recent articles [1, 10], for a discussion of the interesting case that \(n = 1\).

In this work we will focus on the cases where \(\mathcal{A}\) is an \(\mathcal{N} = 4\) or \(\mathcal{N} = 2\) superconformal algebra, though other possibilities exist. In the first case, we demonstrate that any subgroup of \(\text{Co}_0\) that preserves a 3-plane in the 24-dimensional representation can stabilise an \(\mathcal{N} = 4\) structure. The groups that arise are discussed in e.g. Chapter 10 of the book by Conway and Sloane [16]. They include in particular the Mathieu groups \(M_{22}\) and \(M_{11}\). In the second case, where the group need only fix a 2-plane in order to preserve an \(\mathcal{N} = 2\) superconformal algebra, there are again many possibilities (again, see [16]), including the larger Mathieu groups \(M_{23}\) and \(M_{12}\). Note that the larger the superconformal algebra we wish to preserve, the smaller the global symmetry group is. Corresponding to certain specific choices of the \(\mathcal{N} = 0, 1, 2, 4\) algebras, we have the global symmetry groups \(\text{Spin}(24) \supset \text{Co}_0 \supset M_{23} \supset M_{22}\).
We should stress again that there are other $\mathcal{Co}_0$ subgroups that preserve $\mathcal{N} = 4$ resp. $\mathcal{N} = 2$ superconformal algebras arising from 3-planes resp. 2-planes in $24$. Some examples are: the group $\mathcal{U}_4(3)$ for the former case, and the McLaughlin ($\text{McL}$) and Higman–Sims ($\text{HS}$) sporadic groups, and also $\mathcal{U}_6(2)$ for the latter case. However, only for the Mathieu groups do the twined partition functions of the module display uniformly a special property, which we regard as an essential feature of the moonshine phenomena. Namely, all the mock modular forms obtained via twining by elements of the Mathieu groups are encoded in Jacobi forms that are constant in the elliptic variable, in the limit as the modular variable tends to any cusp other than the infinite one. This property also holds for the Jacobi forms of the Mathieu moonshine mentioned above, and may be regarded as a counter-part to the genus zero property of monstrous moonshine, as we explain in more detail in Sect. 8.

The importance of this property is its predictive power: it allows us to write down trace functions for the actions of Mathieu group elements with little more information than a certain fixed multiplier system, and the levels of the functions we expect to find. A priori these are just guesses, but the constructions we present here verify their validity.

This may be compared to the predictive power of the genus zero property of monstrous moonshine: if $\Gamma < \text{SL}_2(\mathbb{R})$ determines a genus zero quotient of the upper-half plane, and if the stabilizer of $i\infty$ in $\Gamma$ is generated by $\pm \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ then there is a unique $\Gamma$-invariant holomorphic function satisfying $T_\Gamma(\tau) = q^{-1} + O(q)$ as $\tau \to i\infty$, for $q = e^{2\pi i \tau}$. The miracle of monstrous moonshine, and the content of the moonshine conjectures of Conway–Norton [15], is that for suitable choices of $\Gamma$, the function $T_\Gamma$ is the trace of an element of the monster on some graded infinite-dimensional module (namely, the moonshine module of [36, 37]). The optimal growth property formulated in [14] plays the analogous predictive role in umbral moonshine, and is similar to the special property we formulate for the Mathieu moonshine considered here.

We mention here that although the moonshine conjectures have been proven in the monstrous case by Borcherds [3], and verified in [7, 28, 43] (see also [6]) for umbral moonshine, conceptual explanations of the genus zero property of monstrous moonshine, and of the analogous properties of umbral moonshine, and the Mathieu moonshine studied here, remain to be determined. An approach to establishing the genus zero property of monstrous moonshine via quantum gravity is discussed in [29].

The organization of the paper is as follows. We begin in Sect. 2 with a review of the module discussed in [27]. In Sect. 3, we describe methods for endowing this module with $\mathcal{N} = 4$ and $\mathcal{N} = 2$ structure. In Sect. 4, we discuss what this does to the manifest symmetry group of the model, reducing the symmetry from $\mathcal{Co}_0$ to a variety of other possible groups which preserve a 3-plane (respectively 2-plane) in the $24$ of $\mathcal{Co}_0$. In Sects. 4 and 5, we discuss the action of these $\mathcal{Co}_0$-subgroups on the modules and compute the corresponding twining functions. We identify $M_{23}$, $M_{22}$, $\text{McL}$, $\text{HS}$, $\mathcal{U}_6(2)$ and $\mathcal{U}_4(3)$ as some of the most interesting $\mathcal{Co}_0$-subgroups preserving some extended superconformal algebra. In Sects. 6 and 7, we discuss in some detail the decomposition of the graded partition function of our chiral conformal field theory into characters of irreducible representations of the $\mathcal{N} = 4$ and $\mathcal{N} = 2$ superconformal algebras. In Sect. 8, we discuss the special property we require from a moonshine twining function, and show how this property singles out the Mathieu groups.
in our setup. We close with a discussion in Sect. 9. The appendices contain a number of tables: character tables for the various groups we discuss, tables of coefficients of the vector-valued mock modular forms that arise as our twining functions, and tables describing the decompositions of our modules into irreducible representations of the various groups.

2 The free field theory

The chiral 2d conformal field theory that will play a starring role in this paper has two different constructions. The first is described in [37] and starts with 8 free bosons $X^i$ compactified on the 8-dimensional torus given by the $E_8$ root lattice, together with their Fermi superpartners $\psi^i$. One then orbifolds by the $\mathbb{Z}_2$ symmetry

$$(X^i, \psi^i) \rightarrow (-X^i, -\psi^i). \tag{2.1}$$

Note that, in more mathematical terms, a chiral 2d conformal field theory can be understood to mean a super vertex operator algebra (usually assumed to be simple, and of CFT-type in the sense of [23]), together with a (simple) canonically-twisted module. These two spaces are referred to as the Neveu–Schwarz (NS) and Ramond (R) sectors of the theory, respectively. The compactification of free bosons on the torus defined by a lattice $L$ manifests, in the NS sector, as the usual lattice vertex algebra construction, and their Fermi superpartners are then realized by a Clifford module, or free fermion, super vertex algebra, where the underlying orthogonal space comes equipped with an isometric embedding of $L$. In the cases under consideration, there is a unique simple canonically-twisted module up to equivalence (cf. e.g. [24]), and hence a unique choice of R sector.

The orbifold procedure is described in detail in the language of vertex algebra in [24]. In what follows, a field of dimension $d$ is a vertex operator or intertwining operator attached to a vector $v$ in the NS or R sector, respectively, with $L(0)v = dv$. A current is a field of dimension 1. A field is called primary if its corresponding vector is a highest weight for the Virasoro (Lie) algebra. A ground state is an $L(0)$-eigenvector of minimal eigenvalue.

The $E_8$ construction just described has manifest $\mathcal{N} = 1$ supersymmetry, in the sense that the Neveu–Schwarz and Ramond algebras act naturally on the NS and R sectors, respectively. After orbifolding we obtain a $c = 12$ theory with no primary fields of dimension $\frac{1}{2}$. The partition functions (i.e., graded dimensions) of this free field theory can easily be computed. For example, the NS sector partition function is given by

$$Z_{\text{NS, } E_8}(\tau) = \frac{1}{2} \left( \frac{E_4(\tau) \theta_3(\tau, 0)^4}{\eta(\tau)^{12}} + 16 \frac{\theta_4(\tau, 0)^4}{\theta_2(\tau, 0)^4} + 16 \frac{\theta_2(\tau, 0)^4}{\theta_4(\tau, 0)^4} \right) \tag{2.2}$$

$$= q^{-1/2} + 0 + 276q^{1/2} + 2048q + 11202q^{3/2} + \cdots, \tag{2.3}$$

where $E_4$ is the weight 4 Eisenstein series, being the theta series of the $E_8$ lattice, $\eta(\tau) = q^{1/24} \prod_{n=1}^{\infty} (1 - q^n)$ is the Dedekind eta function, and $\theta_i$ are the Jacobi theta functions recorded in "Appendix A". We have also set $q = e(\tau)$ and we use the shorthand notation $e(x) = e^{2\pi ix}$ throughout this paper.
One recognizes representations of the $\text{Co}_1$ sporadic group appearing in the $q$-series (2.3): apart from 276, which is the minimal dimension of a faithful irreducible representation (cf. [31]), one can also observe

$$2048 = 1 + 276 + 1771,$$

$$11202 = 1 + 276 + 299 + 1771 + 8855,$$

\ldots

(2.4)

(2.5)

In fact, this theory has a $\text{Co}_0 \cong 2\text{Co}_1$ symmetry, which we call non-manifest since the action of $\text{Co}_0$ is not obvious from the given description. Note that we sometimes use $n$ or $\mathbb{Z}/n\mathbb{Z}$ to denote $\mathbb{Z}/n\mathbb{Z}$ depending on the context.

A better realization, for our purposes, was discussed in detail in [28] (cf. also [40]). The $E_8$ orbifold theory is equivalent to a theory of 24 free chiral fermions $\lambda_1, \lambda_2, \ldots, \lambda_{24}$, also orbifolded by the $\mathbb{Z}_2$ symmetry $\lambda_\alpha \to -\lambda_\alpha$. This gives an alternative description of the Conway module above. The partition function from this “free fermion” point of view is more naturally written as

$$Z_{\text{NS, fermion}}(\tau) = \frac{1}{2} \sum_{i=2}^4 \frac{\vartheta^{12}_i(\tau, 0)}{\eta^{12}(\tau)}.$$  \hspace{1cm} (2.6)

This is equal to (2.2) according to non-trivial identities satisfied by theta functions. Note that $\vartheta_1(\tau, 0) = 0$.

The free fermion theory has a manifest Spin(24) symmetry, but not a manifest $\mathcal{N} = 1$ supersymmetry. However, one can construct an $\mathcal{N} = 1$ supercurrent as follows. There is a unique (up to scale) NS ground state, but there are $2^{12} = 4096$ linearly independent Ramond sector ground states, which may be obtained by acting on a given fixed R sector ground state with the fermion zero modes $\lambda_i(0)$. It will be convenient to label the resulting 4096 Ramond sector ground states by vectors $s \in \tilde{F}_2^{12}$, where $\tilde{F}_2 = \{-1/2, 1/2\}$.

We therefore have 4096 spin fields of dimension $\frac{3}{2}$ which implement the flow from the NS to the R sector. Denoting these fields as $W_s$, one can try to find a linear combination

$$W = \sum_{s \in \tilde{F}_2^{12}} c_s W_s \hspace{1cm} (2.7)$$

which will serve as an $\mathcal{N} = 1$ supercurrent (i.e., field whose modes generate actions of the Neveu–Schwarz and Ramond super Lie algebras). As demonstrated in [28], and as we will review in the next section, there exists a set of values $c_s$ such that the operator product expansion of $W$ and the stress tensor $T$ close properly, defining actions of the Neveu–Schwarz and Ramond algebras.

Any choice of $W$ breaks the Spin(24) symmetry, since the Ramond sector ground states split into two 2048-dimensional irreducible representation of Spin(24). It is proven in [28] that the subgroup of Spin(24) that stabilizes a suitably chosen $\mathcal{N} = 1$ supercurrent is exactly the Conway group $\text{Co}_0$. In brief, the method of [28] is to identify a certain elementary abelian subgroup of order $2^{12}$ in Spin(24) (which should be regarded as a copy of the extended Golay code in Spin(24)). The action of this subgroup on the Ramond sector ground states singles out a particular choice of $W$, with the property that it is not
annihilated by the zero mode of any dimension 1 field in the theory. It follows from this (cf. Proposition 4.8 of [28]) that the subgroup of Spin(24) that stabilizes $W$ is a reductive algebraic group of dimension 0, and hence finite. On the other hand, one can show (cf. Proposition 4.7 of [28]) that this group contains $Co_0$ by virtue of the choice of subgroup $2^{12}$. We obtain that the full stabilizer of $W$ in Spin(24) is $Co_0$ by verifying (cf. Proposition 4.9 of [28]) that $Co_0$ is a maximal subgroup, subject to being finite.

In the rest of this paper, we extend this idea as follows. Instead of choosing an $\mathcal{N} = 1$ supercurrent and viewing the theory as an $\mathcal{N} = 1$ super conformal field theory, we choose various other super extensions of the Virasoro algebra. We will argue that $\mathcal{N} = 4$ and $\mathcal{N} = 2$ superconformal presentations of the theory are in one to one correspondence with choices of subgroups of $Co_0$ which fix a 3-plane (respectively, 2-plane) in the 24 dimensional representation. This leads us naturally to theories with various interesting symmetry groups, whose twining functions are easily computed in terms of the partition function (or elliptic genus) of the free fermion conformal field theory. These functions in turn are expressed nicely in terms of mock modular forms, and thus we establish mock modular moonshine relations for subgroups of $Co_0$ via this family of modules.

### 3 The superconformal algebras

We first discuss the largest superconformal algebra (SCA) we will consider, which gives rise to smaller global symmetry groups. We will construct an $\mathcal{N} = 4$ SCA in the free fermion orbifold theory. Our strategy is to first construct the $SU(2)$ fields, and act with them on an $\mathcal{N} = 1$ supercurrent to generate the full $\mathcal{N} = 4$ SCA. We consequently obtain actions of the $\mathcal{N} = 2$ SCA by virtue of its embeddings in the $\mathcal{N} = 4$ SCA. In this process, we break the $Co_0$ symmetry group down to a proper subgroup as we will discuss in Sect. 4. We refer the reader to [32, 50, 52] for background on the $\mathcal{N} = 4$ and $\mathcal{N} = 2$ superconformal algebras.

We start with 24 real free fermions $\lambda_1, \lambda_2, \ldots, \lambda_{24}$. Picking out the first three fermions, we obtain the currents $J_i$:

$$J_i = -i\epsilon_{ijk} \lambda_j \lambda_k, \quad i, j, k \in \{1, 2, 3\}. \quad (3.1)$$

They form an affine $SU(2)$ algebra with level 2 as may be seen from their operator product expansion (OPE),

$$J_i(z)J_j(0) \sim \frac{1}{z^2} \delta_{ij} + \frac{i}{z} \epsilon_{ijk} J_k(0). \quad (3.2)$$

The next step is to pick an $\mathcal{N} = 1$ supercurrent and act with $J_i$ on it. As we reviewed in Sect. 2, an $\mathcal{N} = 1$ supercurrent exists in this model and may be written as a linear combination of spin fields. Moreover, it may be chosen so that its stabilizer in Spin(24) is precisely $Co_0$. We will present a very general version of the construction now, and then extend it to find the $\mathcal{N} = 4$ SCA.

To write the $\mathcal{N} = 1$ supercurrent explicitly, we first group the 24 real fermions into 12 complex ones and bosonize them:
In terms of the bosonic fields \( H = ( H_1, \ldots, H_{12} ) \), an \( \mathcal{N} = 1 \) supercurrent \( W \) may be written as

\[
W = \sum_{s \in \tilde{F}_{12}} w_s e^{i s \cdot H} c_s(p),
\]

where each component of \( s = ( s_1, s_2, \ldots, s_{12} ) \) takes the values \( \pm 1/2 \), and the coefficients \( w_s \) belong to \( C \). We have introduced cocycle operators \( c_s(p) \) to ensure that the fields with integer spins (i.e., corresponding to even parity vectors) commute with all other operators, and the fields with half integral spins (corresponding to odd parity vectors) anticommute amongst themselves. The cocycle operators depend on the zero-mode operators \( p \) which are characterized by the commutation relation

\[
[p, e^{i k \cdot H}] = k e^{i k \cdot H},
\]

where \( k = (k_1, \ldots, k_{12}) \) is an arbitrary 12-tuple of complex numbers.

The associativity and closure of the OPE of the “dressed” vertex operators

\[
V_k = e^{i k \cdot H} c_k(p)
\]

requires that

\[
c_k(p + k') c_k'(p) = e(k, k') c_{k+k'}(p),
\]

where the \( e(k, k') \) satisfy the 2-cocycle condition

\[
e(k, k') e(k + k', k'') = e(k', k'') e(k, k' + k'').
\]

Moreover, in order for \( V_k \) to have the desired (anti)commutation relation, the condition

\[
e(k, k') = (-1)^{k_1 k_1' + k_2 k_2'} e(k', k)
\]

should be imposed. An explicit description of the cocycle for a general vertex operator \( e^{i k \cdot H} \) may be chosen as

\[
c_k(p) = e^{i \pi k \cdot M \cdot p}
\]

according to [33]. In our case, \( M \) is a 12 \( \times \) 12 matrix that has the block form

\[
M = \begin{pmatrix} M_4 & 0 & 0 \\ 1_4 & M_4 & 0 \\ 1_4 & 1_4 & M_4 \end{pmatrix}, \quad M_4 = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & 1 & 0 \\ -1 & 1 & -1 \end{pmatrix},
\]

where \( 1_4 \) is the 4 \( \times \) 4 matrix with all entries set to 1.

Generically, the OPE of \( W \) with itself is

\[
W(z) W(0) \sim \bar{w} w \left[ \frac{1}{z^3} + \frac{T(0)}{4z} \right] + \frac{\bar{w} \gamma^\alpha \gamma^\beta \gamma^\gamma \lambda_\alpha \lambda_\beta \lambda_\gamma \lambda_\delta(0)}{96z},
\]
where we have defined
\[ \bar{w}_s = w_{-s} c_{-s}(s), \]

\[ \Gamma_{ss'}^{\alpha\beta\gamma\delta} = \left( \Gamma^\alpha \Gamma^\beta \Gamma^\gamma \Gamma^\delta \right)_{ss'} c_{-s} (s' - s) \left( -2s_{\frac{\pi}{2}} \right) \cdots \left( -2s_{\frac{\pi}{2} + 1} \right), \]

for \( \alpha < \beta < \gamma < \delta \). The other components of \( \Gamma_{ss'}^{\alpha\beta\gamma\delta} \) are defined by the requirement that it is totally antisymmetrized. For \( W \) to be an \( N = 1 \) supercurrent, the last terms in (3.12) must vanish,

\[ \bar{w}_s \Gamma_{ss'}^{\alpha\beta\gamma\delta} W = 0, \quad \forall \alpha, \beta, \gamma, \delta \in \{1, 2, \ldots, 12\}, \]

and the first two terms must have the correct normalization,

\[ \bar{ww} = \sum_{s \in \tilde{F}_2} w_{-s} w_s c_s (-s) = 8. \]

From now on we presume to be chosen a solution \( (w_s) \) such that \( W \) is an \( N = 1 \) supercurrent stabilized by \( C_{00} \), as described in Sect. 2.

We may now act with the \( SU(2) \) currents \( J_i \) on our \( N = 1 \) supercurrent \( W \). In order to do this, write the \( SU(2) \) currents in (3.1) in bosonized form,

\[ J_1 = -\frac{1}{2} \left( e^{iH_1} - e^{-iH_1} \right) \left( e^{iH_2} e^{i\pi p_1} + e^{-iH_2} e^{-i\pi p_1} \right), \]

\[ J_2 = \frac{i}{2} \left( e^{iH_1} + e^{-iH_1} \right) \left( e^{iH_2} e^{i\pi p_1} + e^{-iH_2} e^{-i\pi p_1} \right), \]

\[ J_3 = i\partial H_1. \]

Here we have included the cocycles \( e^{\pm i\pi p_1} \). We now extract the singular terms of the OPEs,

\[ J_i(z) W(0) \sim -\frac{i}{2\pi} W_i(0), \]

where \( W_i \) are slightly modified combinations of spin fields,

\[ W_1 = -\sum_s 2s_2 w_{s_2} e^{is H} c_s (p), \]

\[ W_2 = i \sum_s 4s_1 s_2 w_{s_2} e^{is H} c_s (p), \]

\[ W_3 = i \sum_s 2s_1 w_{s_2} e^{is H} c_s (p), \]

and where \( Rs \equiv (\pm s_1, \pm s_2, s_3, \ldots, s_{12}) \).
We claim that all three $W_i$ defined above are valid $\mathcal{N} = 1$ supercurrents. This is because we may obtain, for instance, $W_3$ from $W$ by rotating the 1–2 plane by $\pi$, and the conditions (3.15) and (3.16), for being an $\mathcal{N} = 1$ supercurrent, are invariant under $SO(24)$ rotations. We may obtain $W_2$ and $W_3$ similarly. This shows that each of the $W_i$ is an $\mathcal{N} = 1$ supercurrent.

Furthermore, we can check using the identity (3.15) that the OPEs of the $W_i$ are given by

$$W_i(z)W_j(0) \sim \delta_{ij} \left( \frac{8}{z^3} + \frac{2}{z} T(0) \right) + 2i \epsilon_{ijk} \left( \frac{2}{z^2} J_k(0) + \frac{1}{z} \partial J_k(0) \right), \quad (3.24)$$

$$W(z)W_i(0) \sim -2i \left( \frac{2}{z^2} + \frac{\partial}{z} \right) J_i(0), \quad (3.25)$$

$$J_i(z)W_j(0) \sim \frac{i}{2z} (\delta_{ij} W + \epsilon_{ijk} W_k). \quad (3.26)$$

This shows that $W, W_i$, and $J_i$ together with the stress tensor $T$, defined as

$$T = -\frac{1}{2} \sum_a \lambda_a \partial \lambda_a = -\frac{1}{2} \sum_a \partial H_a \partial H_a, \quad (3.27)$$

form an $\mathcal{N} = 4$ SCA with central charge $c = 12$. We may recombine the four $\mathcal{N} = 1$ supercurrents $W, W_i$ into the more conventional $\mathcal{N} = 4$ supercurrents

$$W_1^\pm \equiv 2^{-1/2} (W \pm i W_3), \quad W_2^\pm \equiv \pm 2^{-1/2} i (W_1 \pm i W_2), \quad (3.28)$$

which transform according to the representation $2 + \bar{2}$ of $SU(2)$. In terms of these supercurrents we obtain the standard (small) $\mathcal{N} = 4$ SCA with central charge $c = 12$, characterized by the following set of OPEs:

$$T(z)T(0) \sim \frac{6}{z^4} + \frac{2}{z^2} T(0) + \frac{1}{z} \partial T(0), \quad (3.29)$$

$$T(z)W_a^\pm(0) \sim \frac{3}{2z^2} W_a^\pm(0) + \frac{1}{z} \partial W_a^\pm(0), \quad (3.30)$$

$$T(z)J_i(0) \sim \frac{1}{z^2} J_i(0) + \frac{1}{z} \partial J_i(0), \quad (3.31)$$

$$W_a^+(z)W_b^-(0) \sim \delta_{ab} \left( \frac{8}{z^3} + \frac{2}{z} T(0) \right) - 2\sigma^i_{ab} \left( \frac{2}{z^2} J_i(0) + \frac{1}{z} \partial J_i(0) \right), \quad (3.32)$$

$$W_a^+(z)W_b^+(0) \sim W_a^-(z)W_b^-(0) \sim 0, \quad (3.33)$$

$$J_i(z)W_a^+(0) \sim -\frac{1}{2z} \sigma^i_{ab} W_b^+(0), \quad (3.34)$$

$$J_i(z)W_a^-(0) \sim \frac{1}{2z} \sigma^i_{ab} W_b^-(0), \quad (3.35)$$
Here $\sigma^i$ are the Pauli matrices.

Now we can generalize our formula for the partition function (2.6) to include a grading by the $U(1)$ charge under the Cartan generator of the $SU(2)$. The $U(1)$ charge operator $j_0$ is, by definition, twice the zero-mode of the $j_3$ current. From this and the definition $j_3 = -i\lambda_1 \lambda_2 = \psi_1 \bar{\psi}_1$, we see that under $j_0$ the complex fermion $\psi_1$ has charge 2 while the other 11 complex fermions are neutral. Therefore, the $U(1)$-graded NS sector partition function becomes

$$Z_{NS}(\tau, z) = \frac{1}{2^4} \sum_{i=2}^{24} \frac{\theta_i(\tau, 2z) \theta_i(\tau, 0)^{11}}{\eta(\tau)^{12}}.$$

(3.37)

In the above discussion, we have chosen the first three fermions out of a total of 24 to generate a set of $SU(2)$ currents. Together with an $\mathcal{N} = 1$ supercurrent they generate a full $\mathcal{N} = 4$ SCA. It is clear that we are free to choose any three fermions for this purpose. In fact, we could choose an arbitrary three-dimensional subspace of the 24-dimensional vector space spanned by the fermions, and obtain an $\mathcal{N} = 4$ SCA. For a given $\mathcal{N} = 1$ supercurrent, not all choices of 3-plane are equivalent, as we will see in Sect. 4.

Observe that we could instead have chosen to single out only two real fermions, and construct a $U(1)$ current algebra instead of an $SU(2)$ current algebra. Completely analogous manipulations then show that each such choice provides an $\mathcal{N} = 2$ superconformal algebra. As a result we can equip the $Co_0$ theory with $\mathcal{N} = 2$ structure in such a way that the global symmetry group is broken to subgroups $G$ of $Co_0$ which stabilize 2-planes in 24.

To summarize the results of this section, we have shown how to construct an $\mathcal{N} = 1$ supercurrent for the chiral conformal field theory described, in the previous section, as an orbifold of 24 free fermions. We have also shown how choices of 2- and 3-planes in the space spanned by the generating fermions give rise to actions of the $\mathcal{N} = 2$ and $\mathcal{N} = 4$ superconformal algebras (respectively) on the theory. As reviewed in Sect. 2, a suitable choice of $\mathcal{N} = 1$ structure reduces the global symmetry of the theory to $Co_0$. In the next section we will discuss the finite simple groups that appear when we impose the richer, $\mathcal{N} = 2$ and $\mathcal{N} = 4$ superconformal structures.

4 Global symmetries

Enhancing the $\mathcal{N} = 1$ structure of the theory to $\mathcal{N} = 4$ breaks the $Co_0$ symmetry. We now show that for a specific choice of 3-plane in 24, resulting in a specific copy of the $\mathcal{N} = 4$ SCA, the stabilising subgroup of $Co_0$ is the sporadic group $M_{22}$. Similarly, for a specific choice of 2-plane, resulting in a specific copy of the $\mathcal{N} = 2$ SCA, the stabilising subgroup of $Co_0$ is the sporadic group $M_{23}$. This amounts to a proof that the model described in Sect. 2 results in an infinite-dimensional $M_{22}$ (resp. $M_{23}$)-module underlying the mock modular forms described in Sect. 6 (resp. Sect. 7) arising from its
interpretation as an $\mathcal{N} = 4$ (resp. $\mathcal{N} = 2$) module. More generally, we establish the modules for 3- (2-)plane-fixing subgroups of the largest Mathieu group $M_{24}$ by fixing a specific copy of $\mathcal{N} = 4$ ($\mathcal{N} = 2$) SCA.

Recall that the theory regarded as an $\mathcal{N} = 0$ theory (i.e., with no extension of the Virasoro action) has a Spin(24) symmetry resulting from the $SO(24)$ rotations on the 24-dimensional space, and a suitable choice of $\mathcal{N} = 1$ supercurrent breaks the Spin(24) group down to its subgroup $Co_0$. The group $Co_0$ is the automorphism group of the Leech lattice $\Lambda_{\text{Leech}}$ and various interesting subgroups of $Co_0$ can be identified as stabilizers of suitably chosen lattice vectors in $\Lambda_{\text{Leech}}$. To study the automorphism group of the module when fixing more structure—more supersymmetries in this case—it will therefore be useful to describe the enhanced supersymmetries in terms of Leech lattice vectors.

In Chapter 10 of [16] it is shown that if we choose an appropriate tetrahedron in the Leech lattice, whose edges have lengths squared $16 \times (2, 2, 2, 2, 3, 3)$ in the normalisation described below, the subgroup of $Co_0$ that leaves all vertices of the tetrahedron invariant is $M_{22}$. To be more precise, let $e_\gamma$ for $\gamma \in \{1, 2, \ldots, 24\}$, be an orthonormal basis of $\mathbb{R}^{24}$, and choose a copy $\mathcal{G}$ of the extended binary Golay code in $V((1, \ldots, 24))$.

Then we may realize $\Lambda_{\text{Leech}}$ as the lattice generated by the vectors $2 \sum_{\gamma \in C} e_\gamma$ for $C \in \mathcal{G}$ together with $-4e_1 + \sum_{\gamma = 1}^{24} e_\gamma$. (One can show that all 24 vectors of the form $-4e_1 + \sum_{\gamma = 1}^{24} e_\gamma$ are in $\Lambda_{\text{Leech}}$) Define the tetrahedron $T_{[\alpha, \beta]}$ by fixing its vertices $O = 0, X_\alpha = 4e_\alpha + \sum_{\gamma = 1}^{24} e_\gamma, X_\beta = 4e_\beta + \sum_{\gamma = 1}^{24} e_\gamma$ and $P_{\alpha \beta} = 4e_\alpha + 4e_\beta$, for any $\alpha, \beta \in \{1, 2, \ldots, 24\}$ with $\alpha \neq \beta$. For every such $T_{[\alpha, \beta]}$, the subgroup fixing every vertex is a copy of $M_{22}$, a sporadic simple group of order $2^7 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11 = 443,520$ and the subgroup of $M_{24}$ fixing $e_\alpha$ and $e_\beta$.

From the above discussion, it is clear that given $\{\alpha, \beta\}$, a copy of $M_{22}$ stabilises the real span of $e_\alpha, e_\beta$ and $\sum_{\gamma = 1}^{24} e_\gamma$. Given a suitable choice of the $\mathcal{N} = 1$ superconformal algebra, this copy of $\mathbb{R}^3$ in $\mathbb{R}^{24}$ then determines, up to rotations, the three fermions, denoted $\lambda_{1,2,3}$, from which the SU(2) current algebra was built in Sect. 3. By definition then, a copy of $M_{22}$ leaves the $\mathcal{N} = 4$ superconformal algebra invariant.

A natural question is: what is the symmetry group $G$ that fixes a given choice of $\mathcal{N} = 2$ superconformal structure? Given the above description of the $M_{22}$ action, we can choose the $\mathbb{R}^2 \subset \mathbb{R}^3$ generated by $e_\alpha$ and $\sum_{\gamma = 1}^{24} e_\gamma$ and use the two free fermions lying in the $\mathbb{R}^2$ to construct the $\mathcal{N} = 2$ sub-algebra of the $\mathcal{N} = 4$ SCA. Specifically, the $U(1)$ action is rotation of the $\mathbb{R}^2$. From the above discussion, it is not hard to see that there is a copy of $M_{23}$ fixing $e_\alpha$ and $\sum_{\gamma = 1}^{24} e_\gamma$ and hence stabilising the $\mathcal{N} = 2$ structure. Recall that $M_{23}$ is a sporadic simple group of order $2^7 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11 \cdot 23 = 10,200,960$. In terms of the Leech lattice, it corresponds to the fact that the stabiliser of the triangle in $\Lambda_{\text{Leech}}$ whose edges have lengths squared $16 \times (6, 3, 2)$, with vertices chosen to be $O, X_\alpha$ and $2 \sum_{\gamma = 1}^{24} e_\gamma$, is a copy of $M_{23}$ inside the copy of $Co_0$ stabilising $\Lambda_{\text{Leech}}$.

This furnishes a proof that the theory described in Sect. 2 leads to modules for $M_{22}$ and $M_{23}$ which explicitly realize the mock modular forms to be defined in Sects. 6 and 7.

We should mention that by stabilizing different choices of geometric structure, other than the tetrahedron and triangle just discussed, leading to $M_{22}$ and $M_{23}$, respectively, we can determine other global symmetry groups $G$. Indeed, our method constructs a $G$-module with $\mathcal{N} = 4$ ($\mathcal{N} = 2$) superconformal symmetry for any subgroup $G < Co_0$. 
which fixes a 3-plane (2-plane) in $\mathbb{P}^4$. Since, as we will see in Sect. 6 (Sect. 7), such modules furnish assignments of mock modular forms to the elements of their global symmetry groups, it is an interesting question to classify the global symmetry groups $G < Co_0$ that can arise. We conclude this section with a discussion of some of these possibilities. Certainly a full classification is beyond the scope of this work, so we restrict our attention (mostly) to sporadic simple examples.

Indeed, the Conway group $Co_0$ is a rich source of sporadic simple groups, for no less than 12 of the 26 sporadic simple groups are involved in $Co_0$ (cf. [17]), in the sense that they may be obtained by taking quotients of subgroups of $Co_0$. Of these 12, all but 3 are actually realised as subgroups, and 6 of these 9 sporadic simple groups appear as subgroups of $Co_0$ fixing (at least) a 2-plane in $\mathbb{P}^4$. These six 2-plane fixing groups are the smaller Mathieu groups, $M_{23}$, $M_{22}$, $M_{12}$ and $M_{11}$, the Higman–Sims group $HS$, and the McLaughlin group $McL$. Some 2-planes they fix are described explicitly in Chapter 10 of [16].

$\mathcal{N} = 4$ modules

From the character tables (cf. [17]) of the six sporadic 2-plane fixing subgroups of $Co_0$ it is clear that $M_{22}$ and $M_{11}$ are the only examples that fix a 3-plane. Even though $M_{11}$ is not a subgroup of $M_{22}$, it turns out that the mock modular forms attached to $M_{11}$ by our $\mathcal{N} = 4$ construction (and the analysis of Sect. 6) are a proper subset of those attached to $M_{22}$, since the conjugacy classes of $Co_0$ appearing in a 3-plane-fixing subgroup $M_{11}$ are a proper subset of those appearing in a subgroup $M_{22}$. For this reason we focus on $M_{22}$ when discussing mock modular forms attached to sporadic simple groups via the $\mathcal{N} = 4$ construction in this work.

If we expand our attention to simple, not necessarily sporadic subgroups of $Co_0$, then there is one example which is larger than $M_{22}$ (which has order 443,520). Namely, the group $U_4(3)$, with order 3,265,920, can arise as the stabilizer of a suitably chosen 3-plane in $\mathbb{P}^4$ of $Co_0$ [16]. The $U_4(3)$ characters are presented in Appendix Table 20, the coefficients in the associated (twined) vector valued mock modular forms in Appendix Tables 3 and 4, and the decomposition of the module into irreducible representations of the group in Appendix Tables 26 and 27.

As we shall see in Sect. 8, the Jacobi forms attached to $M_{22}$ (and therefore also those attached to $M_{11}$) by the $\mathcal{N} = 4$ construction are distinguished in that they satisfy a natural analogue of the genus zero condition of monstrous moonshine. By contrast, this property does not hold for all the Jacobi forms arising from $U_4(3)$. This is the main reason for our focus on $M_{22}$ in the context of $\mathcal{N} = 4$ supersymmetry (Appendix Tables 1, 2, 5, 6, 15).

$\mathcal{N} = 2$ modules

We have focused on the example of $M_{23}$, with order 10,200,960, in this section. Since $M_{22}$ and $M_{11}$ are subgroups of $M_{23}$ we do not consider them further in the context of $\mathcal{N} = 2$ structures. Of the remaining sporadic simple 2-plane-fixing subgroups of $Co_0$, the largest is the McLaughlin group $McL$, which is actually considerably larger than $M_{23}$, having order 898,128,000. Its characters are presented in Appendix Table 21, the coefficients of the (twined) mock modular forms in Appendix Tables 7 and 8, and the decomposition of the module into irreducible representations of the group in Appendix Tables 33, 34, 35, 36, 37, 38.
The next largest example, also larger than $M_{23}$, is the Higman–Sims group $HS$, with order 44,352,000. Its characters are presented in Appendix Table 22, the coefficients of the (twined) mock modular forms in Appendix Tables 9 and 10, and the decomposition of the module into irreducible representations of the group in Appendix Tables 39, 40, 41, 42, 43, 44.

If we expand our attention to simple groups fixing a 2-plane in $24$ then there is one example larger than $McL$. Namely, the group $U_6(2)$, of order 9,196,830,720, fixes any triangle in $24$ whose three sides are vectors of minimal length in the Leech lattice. The characters of $U_6(2)$ are given in Appendix Tables 17, 18, 19, the coefficients of the (twined) mock modular forms in Appendix Tables 11, 12, 13, 14, and the decomposition of the module into irreducible representations of the group in Appendix Tables 45, 46, 47, 48, 49, 50, 51, 52, 53, 54.

In direct analogy with the case of $\mathcal{N} = 4$ structure, it will develop in Sect. 8 that the Jacobi forms attached to $M_{12}$ and $M_{23}$ satisfy a natural analogue of the genus zero condition of monstrous moonshine, and, contrastingly, this property fails in general for the modular forms arising from the other, non-Mathieu, 2-plane-fixing simple groups mentioned above. For these reasons, and since $M_{12}$ is relatively small, we focus on $M_{23}$ in our discussion of $\mathcal{N} = 2$ supersymmetry.

\section{Twining the module}

In the last sections, we have described how to equip the orbifolded free fermion theory with $\mathcal{N} = 4$ and $\mathcal{N} = 2$ superconformal structures. In this section we will use the Ramond sector of our theory to attach two variable formal power series—the $g$-twined graded R sector partition function, cf. (5.10)—to each element $g \in C_0$ that preserves at least a 2-plane in $24$.

Let us denote the Ramond sector by $V$, and let us choose a $U(1)$ charge operator $J_0$. This will be twice the Cartan generator of the $SU(2)$ in the $\mathcal{N} = 4$ case, or the single $U(1)$ generator in the case of $\mathcal{N} = 2$ SCA. Then it is natural to define the Ramond-sector $U(1)$-graded partition function, or elliptic genus,

\begin{equation}
Z(\tau, z) = \text{Tr}_V (-1)^F q^{\frac{1}{2} \frac{c}{24}} y^0 \tag{5.1}
\end{equation}

\begin{equation}
= \frac{1}{2} \frac{1}{\eta^{12}(\tau)} \sum_{i=2}^{4} (-1)^{i+1} \theta_i(\tau, 2z) \theta_i^{11}(\tau, 0) \tag{5.2}
\end{equation}

\begin{equation}
= \frac{1}{2} \frac{E_4(\tau) \theta_1^4(\tau, z)}{\eta^{12}(\tau)} + 8 \sum_{i=2}^{4} \left( \frac{\theta_i(\tau, z)}{\theta_i(\tau, 0)} \right)^4, \tag{5.3}
\end{equation}

where we have introduced a chemical potential for the $J_0$ charges and set $y = e(z)$ for $z \in \mathbb{C}$. Also, we define $(-1)^F$ as an operator on $V$ by requiring that it act as $\text{Id}$ on the untwisted free fermion contribution to $V$, and as $-\text{Id}$ on the twisted fermion contribution.

As is expected for 2d conformal field theories with $\mathcal{N} \geq 2$ supersymmetry, the elliptic genus (5.1) transforms as a Jacobi form of weight 0, index $m = \frac{c}{6}$ and level 1.
Explicitly, and since \( c = 12 \) in our case, this means that \( Z|_2(\lambda, \mu) = Z \) for all \( \lambda, \mu \in \mathbb{Z} \), and \( Z|_{12}\gamma = Z \) for all \( \gamma \in SL_2(\mathbb{Z}) \), where the elliptic and modular slash operators are defined by

\[
(\phi|_m(\lambda, \mu))(\tau, z) = e(m(\lambda^2 \tau + 2i\lambda z))\phi(\tau, z + \lambda \tau + \mu),
\]

\[
(\phi|_{k,m}\gamma)(\tau, z) = e(-m(c\tau + d)(c\tau + d)^{-k})\phi\left(\frac{a\tau + b}{c\tau + d}, \frac{z}{c\tau + d}\right),
\]

respectively, for \( \lambda, \mu \in \mathbb{Z} \) and \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z}) \). (A Jacobi form of level \( N \) is only required to satisfy \( \phi|_{k,m}\gamma = \phi \) for \( \gamma \) in the congruence subgroup \( \Gamma_0(N) \) (cf. (6.24)).)

As we have seen in Sect. 2, the two different ways of writing this function, (5.2) and (5.3), are intuitively connected more closely with the free fermion and \( E_8 \) root lattice descriptions of the theory, respectively. Of course, the \( U(1) \)-graded NS sector partition function (3.37) is related to the above, graded Ramond sector partition function by a spectral flow transformation

\[
Z_{NS}(\tau, z) = q^{1/2}y^{-2}Z(\tau, z - \frac{\tau + 1}{2}).
\]

There is a natural way in which one can twine the above function under certain subgroups of \( Co_0 \). From the previous discussions, we see that the representation 24 plays a central role in the way various subgroups of \( Co_0 \) act on the model. Let’s denote by \( \ell_{g,k} \) and \( \bar{\ell}_{g,k} \), for \( k = 1, \ldots, 12 \), the 12 complex conjugate pairs of eigenvalues of \( g \in Co_0 \) when acting on 24. This information is conveniently encoded in the so-called Frame shape of \( g \) given by

\[
\Pi_g = \prod_n L_n^{m_n}, \quad 1 \leq L_1 < L_2 < L_3 \cdots, \quad \text{and} \quad m_n \in \mathbb{Z}, m_n \neq 0,
\]

satisfying \( \sum_n L_n m_n = 24 \), through the fact that the 12 pairs \( \{\ell_{g,k}, \bar{\ell}_{g,k}\} \) are precisely the 24 roots solving the equation

\[
\prod_n (a^{L_n} - 1)^{m_n} = 0.
\]

As discussed in Sects. 3 and 4, in order to preserve at least \( N = 2 \) superconformal symmetry and hence be able to twine the graded R-sector partition function (5.1), the subgroup \( G \) must leave at least a 2-dimensional subspace in 24 pointwise invariant. In the graded partition function this corresponds to leaving the factor \( \theta_1(\tau, 2\tau) \) in (5.2) invariant. As a result, for every conjugacy class \([g]\) of such a group \( G \) we can choose \( \ell_{g,1} = \bar{\ell}_{g,1} = 1 \). It is easy to see that when acting on the untwisted free fermions of the theory, contributing the terms involving \( \theta_i \) with \( i = 3, 4 \) in (5.2), the group element \( g \) simply replaces \( \theta_i^{11}(\tau, 0) \) with

\[
\prod_{k=2}^{12} \theta_i(\tau, \rho_{g,k}) \quad \text{(5.6)}
\]

where \( e(\rho_{g,k}) = \ell_{g,k} \).
When trying to do the same for the contribution from the twisted fermions, contributing the term involving $\theta_2$ in \eqref{eq:5.2}, however, we see that the above simple consideration suffers from an ambiguity. This can be seen from the fact that $\theta_2(\tau, \rho) = -\theta_2(\tau, \rho + 1)$, and hence the answer cannot be determined simply by looking at the $g$-eigenvalues on $24$. This of course is a reflection of the fact that the global symmetry group, with no superconformal structure imposed, is Spin(24), which is a 2-fold cover of SO(24). As a result, to specify the twining of the twisted fermion contribution, we also need to know the action of $G$ on the faithful $2^{12}$-dimensional representation of Spin(24) spanned by Ramond sector ground states in the free fermion theory (cf. Sect. 2), henceforth denoted $4096$, which decomposes as $4096 = 1 + 276 + 1771 + 24 + 2024$ in terms of the irreducible representations of $Co_0$.

Note that, according to the orbifold construction, just "half" of the Ramond sector ground states in the free fermion theory will contribute to the Ramond sector $V$ of the orbifold theory under consideration. In terms of the $Co_0$ action, the two "halves" are $24 + 2024$, where $Co_0$ acts faithfully, and $1 + 276 + 1771$, where the action factors through $Co_1 = Co_0/2$. In practice, both choices give rise to equivalent theories (i.e., isomorphic super vertex operator algebras, cf. \cite{24, 27}), but they are inequivalent as $Co_0$-modules. For us, the ground states represented by $24 + 2024$ lie in the R sector, $V$, and the $1$ in $1 + 276 + 1771$ represents the $Co_0$-invariant $N = 1$ supercurrent in the NS sector of our orbifold theory.

The above discussion serves to remind us that there is, really, a vanishing term in \eqref{eq:5.2}, which, for certain $g \in Co_0$, will make a non-vanishing contribution to the $g$-twined version of \eqref{eq:5.1}. It vanishes when $g = e$ is the identity because the Ramond sector ground states in the free fermion theory come in pairs with opposite eigenvalues for $(-1)^f$. Moreover, exchanging the pair corresponds to complex conjugation $\psi_a \leftrightarrow \bar{\psi}_a$, for $a = 1, \ldots, 12$, of the complex fermions. Recall that one of the complex fermions, denoted $\psi_1$ in \eqref{eq:3.19}, was used to construct the $U(1)$ charge operator $J_0$, and we are interested in the graded partition function where we introduce a chemical potential $z$ for this operator. Because exchanging $\psi_1 \leftrightarrow \bar{\psi}_1$ also induces a flip of $U(1)$ charges, captured by $z \leftrightarrow -z$, the contribution of the first complex fermion does not vanish, corresponding to the fact that the identity

$$\theta_1(\tau, z) = \theta_1(\tau, z + 2) = -\theta_1(\tau, -z)$$

only forces $\theta_1(\tau, z)$ to vanish at $z \in \mathbb{Z}$. Consequently, the $g$-twining of \eqref{eq:5.7} makes a non-zero contribution to the $g$-twining of \eqref{eq:5.2} if and only if $\rho_{g,k} \not\in \mathbb{Z}$ for all $k = 2, \ldots, 12$. In other words, it is non-zero only when the cyclic group generated by $g$ fixes nothing but a 2-plane.

By inspection we find that, among the groups we consider, such group elements must be in the conjugacy classes $23AB \subset M_{23}$, $6AB, 12AB, 12DE, 18AB \subset U_6(2), 15AB, 30AB \subset McL$, or $20AB \subset HS$. The pairs of these conjugacy classes corresponding to the letters A and B (or D and E) are mutually inverse, and so their respective traces,
on any representation, are related by complex conjugation. In terms of our construction, choosing one over the other is the same as choosing what one labels $\psi_1$ and $\bar{\psi}_1$, and the same as choosing an orientation on the 2-plane fixed by the group element in $24$. As a result, from (5.8) we see that the $\theta_1$ term in the partition functions twined by these conjugate A (D) and B (E) classes come with an opposite sign.

Let us work with the principal branch of the logarithm, and choose $\rho_{g,k} \in [0, 1/2]$ in (5.6). Then, by direct computation—we must compute directly, for the choice of labels for mutually inverse conjugacy classes is not natural—we find that the signs in (5.10) are

$$\epsilon_{g,1} = -1$$

for the inverse classes, $23B \subset M_{23,15A \cup 30A \subset M_{23},12A \cup 12D \cup 6B \cup 18B \subset U_6(2),}$

and $\epsilon_{g,1} = 1$ for the inverse classes, $23B \subset M_{23,15A \cup 30A \subset M_{23},12A \cup 12D \cup 6B \cup 18B \subset U_6(2),}$

Putting these different contributions together, we conclude that for every $[g] \subset G$ where $G$ is a subgroup of $Co_0$ preserving (at least) a 2-plane in $24$, the corresponding $g$-twined $U(1)$-graded R sector partition function reads

$$Z_g(\tau, z) = \frac{1}{\eta(\tau)^{12}} \sum_{i=1}^{\frac{12}{2}} (-1)^{i+1}\epsilon_{g,i}(\tau, 2z) \prod_{k=2}^{12} \theta_i(\tau, \rho_{g,k})$$

where

$$\epsilon_{g,2} = \begin{cases} \frac{T_{ram06g}}{2^{12} \prod_{k=1}^{12} \cos(\pi \rho_{g,k})} & \epsilon_{g,1} \in \{-1, 1\} \\
0 & \text{when } \prod_{k=1}^{12} \cos(\pi \rho_{g,k}) = 0 \end{cases}$$

$$\epsilon_{g,3} = \epsilon_{g,4} = 1,$$

and where the $\epsilon_{g,i}$ are as determined in the preceding paragraph.

In this section we have introduced the $g$-twined $U(1)$-graded Ramond sector partition function, or $g$-twined elliptic genus of our theory, $Z_g$, for any $g \in Co_0$ fixing a 2-plane in $24$. We have also derived an explicit formula (5.10) for $Z_g$, in terms of the Frame shapes $\Pi_g$ and values $T_{ram06g}$. This Frame shape and trace value data is collected, for $g \in G$, for various $G \subset Co_0$ in “Appendix B”. In Sects. 6 and 7 we will see how the above twining leads to the mock modular forms playing the role of the McKay–Thompson series in these new examples of mock modular moonshine.

6 The $\mathcal{N} = 4$ decompositions

From the discussion in Sect. 3 it is clear that the orbifold theory discussed in Sect. 2 can be equipped with $\mathcal{N} = 4$ superconformal structure. In this section we will study the decomposition of the Ramond sector $V$ into irreducible representations of the $\mathcal{N} = 4$
SCA and see how the decomposition leads to mock modular forms relevant for the $M_{22}$ moonshine which we will discuss in Sect. 8.

Recall (cf. [32]) that the $\mathcal{N} = 4$ superconformal algebra contains subalgebras isomorphic to the affine $SU(2)$ and Virasoro Lie algebras. In a unitary representation the former of these acts with level $m - 1$, for some integer $m > 1$, and the latter with central charge $c = 6(m-1)$.

The unitary irreducible highest weight representations $\nu_{m;h,j}^\mathcal{N}=4$ are labeled by the eigenvalues of $L_0$ and $\frac{1}{2}J_0^3$ acting on the highest weight state, which we denote by $\hbar$ and $j$, respectively. Cf. [33, 34]. The superconformal algebra has two types of highest weight Ramond sector representations: the massless (or BPS) representations with $h = \frac{c}{24} = \frac{m-1}{4}$ and $j \in \{0, \frac{1}{2}, \ldots, \frac{m-1}{2}\}$, and the massive (or non-BPS) representations with $h > \frac{m-1}{4}$ and $j \in \{\frac{1}{2}, 1, \ldots, \frac{m-1}{2}\}$. Their graded characters, defined as

$$\text{ch}_{m;h,j}^\mathcal{N}=4(\tau, z) = \text{tr}_{\nu_{m;h,j}^\mathcal{N}=4}\left((-1)^j y^{\frac{1}{2}h - \frac{1}{24}} q^{L_0-c/24}\right), \quad (6.1)$$

are given by

$$\text{ch}_{m;h,j}^\mathcal{N}=4(\tau, z) = (\Psi_{1,1}(\tau, z))^{-1} \mu_{m;j}(\tau, z) \quad (6.2)$$

and

$$\text{ch}_{m;h,j}^\mathcal{N}=4(\tau, z) = (\Psi_{1,1}(\tau, z))^{-1} q^{h-\frac{n^2}{m}} \left(\theta_{m,2j}(\tau, z) - \theta_{m,-2j}(\tau, z)\right) \quad (6.3)$$

in the massless and massive cases, respectively, [34]. In the above formulas, the function $\mu_{m;j}(\tau, z)$ is defined by setting

$$\mu_{m;j}(\tau, z) = (-1)^{1 + 2j} \sum_{k \in \mathbb{Z}} q^{mk^2} z^{2mk} \frac{(yq^k)^{-2j} + (yq^k)^{-2j+1} + \cdots + (yq^k)^{1+2j}}{1 - yq^k}, \quad (6.4)$$

and $\Psi_{1,1}$ is a meromorphic Jacobi form (cf. Sect. 8 of [19] for more on meromorphic Jacobi forms) of weight 1 and index 1 given by

$$\Psi_{1,1}(\tau, z) = -i \frac{\theta_1(\tau, 2z) \eta(\tau)^3}{(\theta_1(\tau, z))^2} = \frac{y+1}{y-1} - (y^2 - y^{-2})q + \cdots. \quad (6.5)$$

Finally, we have used the theta functions

$$\theta_{m,r}(\tau, z) = \sum_{k=r \mod 2m} \exp\left(\frac{k^2}{2}\right) q^{k^2/2m} y^k, \quad (6.6)$$

defined for all $2m \in \mathbb{Z}_{>0}$ and $r - m \in \mathbb{Z}$, and satisfying

$$\theta_{m,r}(\tau, z) = \theta_{m,r+2m}(\tau, z) = e(m) \theta_{m,-r}(\tau, -z).$$

Note that the vector-valued theta function $\theta_m = (\theta_{m,r})$, $r - m \in \mathbb{Z}/2m\mathbb{Z}$, is a vector-valued Jacobi form of weight 1/2 and index $m$ satisfying

...
\[
\theta_m(\tau, z) = \sqrt{\frac{1}{2m}} \sqrt{\frac{i}{\tau}} e^{-\frac{m}{\tau} \tau^2} S_0 \theta_m(-\frac{1}{\tau}, \frac{z}{\tau}) \\
= T_0 \theta_m(\tau + 1, z) \\
= \theta_m(\tau, z + 1) = e(m(\tau + 2z + 1)) \theta_m(\tau, z + \tau),
\]
(6.7)

where the \( S_0 \) and \( T_0 \) matrices are \( 2m \times 2m \) matrices with entries
\[
(S_0)_{r,r'} = e\left(\frac{r' + r}{2m}\right), \quad (T_0)_{r,r'} = e\left(-\frac{r'}{4m}\right) \delta_{r,r'}.
\]
(6.8)

We will take \( m \in \mathbb{Z} \) for the rest of this section. When we consider \( N = 2 \) decompositions in the next section, we will use the theta function with half-integral indices.

From the above discussion, it is clear that the graded partition function of a module for the \( c = 6(m - 1) \), \( N = 4 \) SCA admits the following decomposition
\[
Z_{N=4,m} = \sum_{n \geq 0, 0 \leq r \leq m-1 \atop r \neq 0 \text{ when } n > 0} c_r'(n - \frac{r^2}{4m}) \text{ch}^{N=4}_{m, \frac{r}{4} + n \frac{1}{2}} (\tau, z).
\]
(6.9)

Furthermore, from the identity
\[
\mu_{m, \frac{1}{2}} = (-1)^r (r + 1) \mu_{m, 0} + (-1)^{r-1} \sum_{n \geq 0} n q^{\frac{(r-n+1)^2}{4m}} (\theta_{m,n-r+1} - \theta_{m,-r-n+1})
\]
we arrive at
\[
Z_{N=4,m} = \left(\Psi_{1,1}(\tau, z)\right)^{-1} \left(c_0 \mu_{m, 0}(\tau, z) + \sum_{r \in \mathbb{Z}/2m\mathbb{Z}} F_r^{(m)}(\tau) \theta_{m,r}(\tau, z)\right),
\]
(6.10)

where
\[
F_r^{(m)}(\tau) = \sum_{n=0}^{\infty} c_r\left(n - \frac{r^2}{4m}\right) q^{n - \frac{r^2}{4m}}, \quad 1 \leq r \leq m - 1,
\]
(6.11)

\[
c_0 = \sum_{r=0}^{m-1} (-1)^r (r + 1) c_r'\left(-\frac{r^2}{4m}\right),
\]
(6.12)

\[
c_r\left(n - \frac{r^2}{4m}\right) = \begin{cases} 
\sum_{r'=0}^{m-1} (-1)^{r'-r} (r' + 1 - r) c_{r'}\left(-\frac{r'^2}{4m}\right), & n = 0 \\
c_r\left(n - \frac{r^2}{4m}\right), & n > 0.
\end{cases}
\]
(6.13)

The rest of the components of \( F^{(m)} = (F_r^{(m)}), r \in \mathbb{Z}/2m\mathbb{Z}, \) are defined by setting
\[
F_r^{(m)}(\tau) = -F_{-r}^{(m)}(\tau) = F_{r+2m}^{(m)}(\tau).
\]
(6.14)
Recall that \( \mu_{m;0}(\tau, z) = -f_0^{(m)}(\tau, z) + f_0^{(m)}(\tau, -z) \), a specialisation of the Appell–Lerch sum

\[
  f_u^{(m)}(\tau, z) = \sum_{k \in \mathbb{Z}} \frac{q^{nk^2}y^{2nk}}{1 - yq^4e(-u)}
\]  

(studied in [64], has the following relation to the modular group \( SL_2(\mathbb{Z}) \); let the (non-holomorphic) completion of \( \mu_{m;0}(\tau, z) \) be

\[
  \hat{\mu}_{m;0}(\tau, \bar{z}, z) = \mu_{m;0}(\tau, z) - e\left(\frac{-1}{8}\right) \frac{1}{\sqrt{2m}} \times \sum_{r \in \mathbb{Z}/2m\mathbb{Z}} \theta_{m,r}(\tau, z) \int_{-\bar{z}}^{i\infty}(\tau' + \tau)^{-1/2}S_{m,r}(-\tau') \, d\tau'.
\]  

Then \( \hat{\mu}_{m;0} \) transforms like a Jacobi form of weight 1 and index \( m \) for \( SL_2(\mathbb{Z}) \times \mathbb{Z}^2 \). Here \( S_m = (S_{m,r}) \) is the vector-valued cusp form for \( SL_2(\mathbb{Z}) \) whose components are given by the unary theta functions

\[
  S_{m,r}(\tau) = \sum_{k = r \mod 2m} e\left(\frac{k}{r}\right) k q^{k^2/4m} = \frac{1}{2\pi i} \frac{\partial}{\partial z} \theta_{m,r}(\tau, z)|_{z=0}.
\]  

For later use, note that the theta series \( S_{m,r}(\tau) \) is defined for all \( 2m \in \mathbb{Z} \) and \( r - m \in \mathbb{Z}/2m\mathbb{Z} \).

The way in which the functions \( Z^{(m)}(\tau) \) and \( \hat{\mu}_{m;0} \) transform under the Jacobi group shows that the non-holomorphic function \( \sum_{r \in \mathbb{Z}/2m\mathbb{Z}} \hat{F}_r^{(m)}(\tau) \theta_{m,r}(\tau, z) \) transforms as a Jacobi form of weight 1 and index \( m \) under \( SL_2(\mathbb{Z}) \times \mathbb{Z}^2 \), where

\[
  \hat{F}_r^{(m)}(\tau) = F_r^{(m)}(\tau) + c_0 e\left(\frac{-1}{8}\right) \frac{1}{\sqrt{2m}} \int_{-\bar{z}}^{i\infty}(\tau' + \tau)^{-1/2}S_{m,r}(-\tau') \, d\tau'.
\]  

In other words, \( F^{(m)} = (F_r^{(m)}) \), \( r \in \mathbb{Z}/2m\mathbb{Z} \) is a vector-valued mock modular form with a vector-valued shadow \( c_0 S_m \), whose \( r \)-th component is given by \( S_{m,r}(\tau) \), with the multiplier for \( SL_2(\mathbb{Z}) \) given by the inverse of the multiplier system of \( S_m \) (cf. (6.8)).

Now we are ready to apply the above discussion to the \( U(1) \)-graded Ramond sector partition function of the theory, discussed in Sect. 5. Recall that in this case we have \( c = 12 \), so \( m = 3 \) in (6.2) and (6.3). The \( N = 4 \) decomposition of (5.1) gives

\[
  Z(\tau, z) = 21 \, \text{ch}^{N=4}_{3,\frac{1}{2},0} + \text{ch}^{N=4}_{3,\frac{1}{2},1} + (560 \, \text{ch}^{N=4}_{3,\frac{1}{2},0} + 8470 \, \text{ch}^{N=4}_{3,\frac{1}{2},1} + 70576 \, \text{ch}^{N=4}_{3,\frac{1}{2},1}) + (210 \, \text{ch}^{N=4}_{3,\frac{1}{2},1} + 4444 \, \text{ch}^{N=4}_{3,\frac{1}{2},1} + 42560 \, \text{ch}^{N=4}_{3,\frac{1}{2},1} + \cdots)
\]  

\[
  = (\Psi_{1,1}(\tau, z))^{-1}\left(24 \mu_{3;0}(\tau, z) + \sum_{r \in \mathbb{Z}/6\mathbb{Z}} h_r(\tau) \theta_{3,r}(\tau, z)\right)
\]  

(6.18)
where \( \ldots \) stand for terms with expansion \( \Psi_{1,1}^{-1} q^\alpha y^\beta \) with \( \alpha - \beta^2/12 > 3 \). More Fourier coefficients of the functions \( h_r(\tau) \) are recorded in "Appendix C," where \( h = h_g \) for \( [g] = 1A \). Note that all the graded multiplicities \( c_\ell(n - \frac{r^2}{12}) \) appear to be non-negative. Of course, this is guaranteed by the fact that \( V \) is a module for the \( \mathcal{N} = 4 \) SCA as shown in Sect. 3. In particular, the Fourier coefficients of \( h_r(\tau) \) appear to be all non-negative apart from that of the polar term \(-2q^{-1/12}\) in \( h_1 \).

From the above discussion we see that \( h \equiv (h_r) \), for \( r \in \mathbb{Z}/6\mathbb{Z} \), is a weight 1/2 vector-valued mock modular form for \( \text{SL}_2(\mathbb{Z}) \) with 6 components (but just 2 linearly independent components, since \( h_0 = h_3 = 0 \), \( h_{-1} = -h_1 \), and \( h_{-2} = -h_2 \)), with shadow given by \( 24S_2 \) and multiplier system inverse to that of \( S_3 \).

This is to be contrasted with the elliptic genus of a generic non-chiral super conformal field theory. For example, the sigma model of a K3 surface has \( c = 6 \), and the elliptic genus is given by

\[
\text{EG}(\tau, z; K3) = \text{Tr}_{H_{6,6}} (-1)^F c_F \chi_{L}^q \chi_{R}^{12q} q^{-1} = 20 \chi_{L}^{N=4} - 2 \chi_{L}^{N=1} + (90 \chi_{L}^{N=4} + 462 \chi_{L}^{N=4} + 1540 \chi_{L}^{N=4} + \cdots )
\]

(6.19)

\[
= (\Psi_{1,1}(\tau, z))^{-1} \left\{ 24 \mu_{2,0}(\tau, z) + (\theta_{2,1}(\tau, z) - \theta_{2,-1}(\tau, z)) \right\}
\]

(6.20)

where \( \ldots \) stand for terms with expansion \( \Psi_{1,1}^{-1} q^\alpha y^\beta \) with \( \alpha - \beta^2/8 > 3 \). In this case, the coefficient multiplying the massless character \( \chi_{L}^{N=4} \) is negative, arising from the Witten index of the right-moving massless multiplets paired with the representation \( \nu_{\nu}^{N=4} \) of the left-moving \( \mathcal{N} = 4 \) SCA.

In Sect. 3 we have shown that the theory under consideration, as a module for the \( \mathcal{N} = 4 \) SCA, admits a faithful action via automorphisms by a group \( G \), as long as \( G \) is a subgroup of \( \text{Co}_0 \) fixing at least a 3-plane. For any such \( g \in G \), the \( g \)-twined graded partition function \( Z_g(\tau, z) \) is given by \( (5.10) \), and from the fact that the action of \( g \) commutes with the \( \mathcal{N} = 4 \) SCA, we expect \( Z_g(\tau, z) \) to admit a decomposition

\[
Z_g(\tau, z) = (\Psi_{1,1}(\tau, z))^{-1} \left( (\text{Tr}_{24g}) \mu_{3,0}(\tau, z) + \sum_{r \in \mathbb{Z}/6\mathbb{Z}} h_{g,r}(\tau) \theta_{3,r}(\tau, z) \right).
\]

(6.21)

Moreover, the coefficients of

\[
h_{g,r}(\tau) = a_r q^{-r^2/12} + \sum_{n=1}^{\infty} (\text{Tr}_{V_{r,n}^G}) q^{n-r^2/12}
\]

(6.22)

must be characters of the \( G \)-module

\[
V^G = \bigoplus_{r=1,2} \bigoplus_{n=1}^{\infty} V_{r,n}^G
\]

(6.23)
arising from the orbifold theory discussed in Sect. 2.

Indeed, the multiplicities of the $\mathcal{N} = 4$ multiplets in the decomposition (6.17) are suggestive of the following group theoretic interpretation: the 21 $h = 1/2$, $j = 0$ massless representations transform as the 21-dimensional irreducible representation of $M_{22}$, and similarly, the 560 $h = 3/2$, $j = 1/2$ massive representations transform as $\chi_{10} + \chi_{11}$ (see “Appendix B”), or “280 + 280”, under $M_{22}$, etc.

We have explicitly computed the first 30 or so coefficients of each $q$-series $h_{g,r}(\tau)$ for all conjugacy classes $[g]$ of $G$, for $G = M_{22}$ and $G = U_4(3)$. These can be found in the tables in “Appendix C”. Subsequently, we compute the first 30 or so $G$-modules $V_{g,n}$ in terms of their decompositions into irreducible representations. They can be found in the tables in “Appendix D”.

Finally we would like to discuss the mock modular property of the functions $h_g = (h_{g,r})$. Recall that the Hecke congruence subgroups of $\text{SL}_2(\mathbb{Z})$ are defined as

\[
\Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{Z}) \mid c \equiv 0 \text{ mod } N \right\}.
\]

(6.24)

We expect $Z_g$ to be a weak Jacobi form of weight zero and index 2 (possibly with multiplier) for the group $\Gamma_0(o_g) \times \mathbb{Z}^2$, where $o_g$ is the order of the group element $g \in G$. This can be verified explicitly from the expression (5.10). Repeating the similar arguments as above, we conclude that each vector-valued function $h_g$ is a vector-valued mock modular form of weight $1/2$ with shadow $(\text{Tr}_{24} g) S_3$ for the congruence subgroup $\Gamma_0(o_g)$. Note that $(\text{Tr}_{24} g) \neq 0$ for all $g \in M_{22}$ which are the cases of our main interest. For these cases the multiplier of $h_g$ is again given by the inverse of the multiplier system of $S_3$, now restricted to $\Gamma_0(o_g)$.

In this section we have analyzed the decomposition of the Ramond sector of our orbifold theory into irreducible modules for the $\mathcal{N} = 4$ SCA, and we have demonstrated that the generating functions of irreducible $\mathcal{N} = 4$ SCA module multiplicities furnish a vector-valued mock modular form. We have also demonstrated that these multiplicities are dimensions of modules for subgroups $G < C_{00}$ that point-wise fix a 3-plane in 24, and we have analyzed the modularity of the resulting, $g$-twined multiplicity generating functions, for $g \in G$. We have verified that each such $g$-twining results in a vector-valued mock modular form with a specified shadow function. In the next section we will present directly analogous considerations for $\mathcal{N} = 2$ superconformal structures arising from 2-planes in 24.

7 The $\mathcal{N} = 2$ decompositions

As discussed in Sect. 4, the theory presented in Sect. 2 can be regarded as a module for an $\mathcal{N} = 2$ SCA as well as for an $\mathcal{N} = 4$ SCA. Moreover, for every subgroup $G < C_{00}$ fixing a 2-plane there is an $\mathcal{N} = 2$ SCA commuting with the action of $G$ on the theory. As a result, and as we will now demonstrate, the decomposition of the partition function (5.10) twined by elements of $G$ into $\mathcal{N} = 2$ characters leads to sets of vector-valued mock modular forms, now of weight $1/2$ and index $3/2$, which are the graded characters of an infinite-dimensional $G$-module inherited from the $C_{00}$-module structure on $V$ (cf. Sect. 5).
To see what these (vector-valued) mock modular forms \( \hat{h}_g = (\hat{h}_g) \) are, let us start by recalling the characters of the irreducible representations of the \( \mathcal{N} = 2 \) SCA. For the SCA with central charge \( c = 3(2\ell + 1) = 3\hat{c} \), the unitary irreducible highest weight representations \( y_{\ell,h,Q}^{\mathcal{N}=2} \) are labeled by the two quantum numbers \( h \) and \( Q \) which are the eigenvalues of \( L_0 \) and \( J_0 \), respectively, when acting on the highest weight state \([22, 51]\). Just as in the \( \mathcal{N} = 4 \) case, there are two types of Ramond sector highest weight representations: the massless (or BPS) representations with \( h = \frac{c}{24} = \frac{\hat{c}}{8} \) and \( Q \in \{ -\frac{\hat{c}}{4} + 1, -\frac{\hat{c}}{4} + 2, \ldots, \frac{\hat{c}}{4} - 1, \frac{\hat{c}}{4} \} \), and the massive (or non-BPS) representations with \( h > \frac{c}{8} \) and \( Q \in \{ -\frac{\hat{c}}{2} + 1, -\frac{\hat{c}}{2} + 2, \ldots, \frac{\hat{c}}{2} - 2, \frac{\hat{c}}{2} - \frac{1}{2}, \frac{\hat{c}}{2} \} \), \( Q \neq 0 \). From now on we will concentrate on the case when \( \ell \) is half-integral, and hence \( \hat{c} \) and \( c \) are even.

The graded characters, defined as

\[
\text{ch}_{\ell,h,Q}^{\mathcal{N}=2}(\tau, z) = \text{tr}_{y^{\mathcal{N}=2}}((-1)^J y^J q^{L_0-c/24}),
\]

are given by

\[
\text{ch}_{\ell,h,Q}^{\mathcal{N}=2}(\tau, z) = e\left(\frac{Q}{2}\right)(\Psi_{h-z/2}^-)(\tau, z))^{-1} q^{\ell h - \frac{c}{8} - \frac{c}{2}\pi i} \theta_{4\ell}(\tau, z),
\]

\[
j = \text{sgn}(Q) (|Q| - 1/2),
\]

for the massive representations, and

\[
\text{ch}_{\ell,c/24,Q}^{\mathcal{N}=2}(\tau, z) = e\left(\frac{\ell+Q+1/2}{2}\right)(\Psi_{1-h/2}^-)(\tau, z))^{-1} y^{Q+1/2} f_{\ell/2}(\tau, z + u),
\]

\[
u = \frac{1}{2} + \frac{(1+2Q)e}{4\ell},
\]

for the massless representations (with \( Q \neq \frac{\hat{c}}{2} \)). The character \( \text{ch}_{\ell,c/24,Q}^{\mathcal{N}=2}(\tau, z) \) for \( Q = \frac{\hat{c}}{2} \) is given in (7.5). In the above formula, we have used the Appell–Lerch sum (6.15) and defined

\[
\Psi_{h-z/2}^- = -i \frac{\eta(\tau)^3}{\theta_1(\tau, z)} = \frac{1}{y^{1/2} - y^{-1/2}} + q (y^{1/2} - y^{-1/2}) + O(q^2).
\]

Note that the above characters transform according to the rule

\[
\text{ch}_{\ell,c/24,Q}^{\mathcal{N}=2}(\tau, z) = \text{ch}_{\ell,c/24,-Q}^{\mathcal{N}=2}(\tau, -z)
\]

under charge conjugation.

From the relation between the massless and massive characters

\[
\text{ch}_{\ell,c/24,Q}^{\mathcal{N}=2} = q^{-n} \sum_{k=0}^{(Q-1)/2} (-1)^k \left( \text{ch}_{\ell,n+c/24,Q-k}^{\mathcal{N}=2} + \text{ch}_{\ell,n+c/24,k-Q}^{\mathcal{N}=2} \right) + 2(-1)^{Q} \text{ch}_{\ell,c/24,0}^{\mathcal{N}=2}, \quad n > 0, |Q| \leq \ell,
\]

\[
\text{ch}_{\ell,c/24,1/2}^{\mathcal{N}=2} = q^{-n} \left( \text{ch}_{\ell,n+c/24,1/2}^{\mathcal{N}=2} + \sum_{k=1}^{(Q)/2} (-1)^k \left( \text{ch}_{\ell,n+c/24,1/2-k}^{\mathcal{N}=2} + \text{ch}_{\ell,n+c/24,k-1/2}^{\mathcal{N}=2} \right) \right) + (-1)^{Q} \text{ch}_{\ell,c/24,0}^{\mathcal{N}=2},
\]

(7.4)
as well as the charge conjugation symmetry of the theory, we expect the $U(1)$-graded Ramond sector partition function of a theory that is invariant under charge conjugation to admit a decomposition

\[ Z^{N=2,\ell} = C_0 \, \text{ch}_{N=2}^{2,\ell}(\tau, z) + \sum_{n \geq 0} C'_n (n - \frac{j}{4\ell}) \, \text{ch}_{N=2}^{2,\ell+n,\frac{1}{2}}(\tau, z) < \text{error} - \]

\[ + \sum_{n \geq 0, j \in \{\frac{1}{2}, \ldots, \ell-1\}} C'_j (n - \frac{j}{4\ell}) \left( \text{ch}_{N=2}^{2,\ell+n,\frac{1}{2}}(\tau, z) + \text{ch}_{N=2}^{2,\ell+n,-\frac{1}{2}}(\tau, z) \right) \]

(7.6)

\[ = e(\frac{j}{2})(\Psi_1, -\frac{1}{2})^{-1} \left( C_0 \tilde{\mu}_{\ell,0}(\tau, z) + \sum_{j \in \mathbb{Z}/2\ell\mathbb{Z}} \tilde{F}_j^{(\ell)}(\tau) \theta_{\ell,j}(\tau, z) \right) \]

(7.7)

when the $N = 2$ SCA has even central charge, $c = 3(2\ell + 1)$. In the last equation, we have defined

\[ \tilde{\mu}_{\ell,0} = e(\frac{j}{4}) y^{1/2} F_j^{(\ell)}(\tau, u + z), \quad u = \frac{1}{2} + \frac{r}{4\ell}, \]

and

\[ \tilde{F}_j^{(\ell)}(\tau) = \tilde{F}_{-j}^{(\ell)}(\tau) = \tilde{F}_{j+2\ell}^{(\ell)}(\tau) = \sum_{n \geq 0} C'_j (n - \frac{j}{4\ell}) q^n q^{\frac{j^2}{4\ell}}, \]

(7.8)

\[ C_0 = C_0' + 2 \sum_{j \in \{\frac{1}{2}, \ldots, \ell\}} (-1)^{j+1} \frac{j^2}{4\ell} C'_j \left( -\frac{j^2}{4\ell} \right) \]

(7.9)

\[ C'_j (n - \frac{j}{4\ell}) = \begin{cases} \sum_{k=0}^{\ell-j} (-1)^k C'_{j+k} \left( -\frac{(j+k)^2}{4\ell} \right) & n = 0 \\ C'_j (n - \frac{j}{4\ell}) & n > 0. \end{cases} \]

(7.10)

Similar to the case of massless $N = 4$ characters, through its relation to the Appell–Lerch sum, $\tilde{\mu}_{\ell,0}$ admits a completion which transforms as a weight one, half-integral index Jacobi form under the Jacobi group. More precisely, define $\tilde{\mu}_{\ell,0}$ by replacing $\mu_{m,0}$ with $\tilde{\mu}_{\ell,0}$ and the integer $m$ with the half-integral $\ell$ in (6.16). Then $\tilde{\mu}_{\ell,0}$ transforms like a Jacobi form of weight 1 and index $\ell$ under the group $SL_2(\mathbb{Z}) \ltimes \mathbb{Z}^2$. Following the same computation as in the previous section, we hence conclude that $\tilde{F}^{(\ell)} = (\tilde{F}_j^{(\ell)})$, where $j - 1/2 \in \mathbb{Z}/2\ell\mathbb{Z}$, is a vector-valued mock modular form with a vector-valued shadow $C_0 S_{\ell} = C_0(S_{\ell,j}(\tau))$.

Now we are ready to apply the above discussion to the $U(1)$-graded $R$ sector partition function of the orbifold theory of Sect. 2. The $N = 2$ decomposition gives

\[ Z(\tau, z) = 23 \text{ch}_{\frac{3}{2},4}^{N=2} + \text{ch}_{\frac{3}{2},\frac{1}{2}}^{N=2} + \left( 770 \left( \text{ch}_{\frac{3}{2},1}^{N=2} + \text{ch}_{\frac{3}{2},-1}^{N=2} \right) + 13915 \left( \text{ch}_{\frac{3}{2},\frac{1}{2}}^{N=2} + \text{ch}_{\frac{3}{2},-\frac{1}{2}}^{N=2} \right) + \cdots \right) + \left( 231 \text{ch}_{\frac{3}{2},\frac{1}{2}}^{N=2} + 5796 \text{ch}_{\frac{3}{2},\frac{3}{2}}^{N=2} + \cdots \right) \]

(7.11)
where \(\cdots\) denote the terms with expansion \(\Psi^{-1}_{1,-1/2} q^{\alpha} y^\beta\) with \(\alpha - \beta^2/6 > 2\). Again, we observe that all the multiplicities of the representations with characters \(\chi_{N=2}^{G,h}Q\) appear to be non-negative, consistent with our construction of \(V\) as an \(\mathcal{N} = 2\) SCA module.

In general, from the previous sections we have seen that the graded partition function twisted by any element \(g\) of a subgroup \(G\) of \(Co_0\) should admit a decomposition into \(\mathcal{N} = 2\) characters. We write

\[
Z_g(\tau, z) = e(\frac{3}{4}) \Psi^{-1}_{1,-1/2} \left( (\text{Tr}_{24G}) \hat{\mu}_{1/2,0}(\tau, z) + \sum_{j \in \{1/2, -1/2, 3/2\}} \hat{h}_{g,j}(\tau) \theta_{1/2,j} \right). \tag{7.13}
\]

Moreover, from the discussion in Sect. 2 we have seen that

\[
\hat{h}_{g,1/2}(\tau) = \overline{\hat{h}_{g,-1/2}(-\bar{\tau})}, \tag{7.14}
\]

and the coefficients of these functions

\[
\hat{h}_{g,j}(\tau) = a_j q^{-\beta/6} + \sum_{n=1}^{\infty} (\text{Tr}_{\tilde{V}_G^G}) q^{n-\beta/6} \tag{7.15}
\]

are given by characters of a \(G\)-module

\[
\tilde{V}_G^G = \bigoplus_{j=-1/2, 1/2, 3/2} \bigoplus_{n=1}^{\infty} \tilde{V}_{j,n}^G \tag{7.16}
\]

which descends from the orbifold theory in Sect. 2. In particular, for any \(n\), the \(G\)-module \(\tilde{V}_{-1/2,n}^G\) is the dual of \(\tilde{V}_{1/2,n}^G\). From the above discussion, we conclude that \(\hat{h}_{g,1/2} = \overline{\hat{h}_{g,-1/2}}\) is a vector-valued mock modular form for \(\Gamma_0(o_g)\) with shadow \((\text{Tr}_{24G})S_{3/2}\). Recall that \((\text{Tr}_{24G}) \neq 0\) for all \(g \in M_{22}\) which are the cases of our main interest. For these case the multiplier of \(\hat{h}_g\) is given by the inverse of the multiplier system of \(S_{3/2}\) restricted to \(\Gamma_0(o_g)\).

To summarize, we have analyzed the decomposition of the Ramond sector of our orbifold theory into irreducible modules for the \(\mathcal{N} = 2\) SCA in this section, and we have demonstrated that the generating functions of irreducible \(\mathcal{N} = 2\) SCA module multiplicities also furnish a vector-valued mock modular form. We have demonstrated that these multiplicities are dimensions of modules for subgroups \(G < Co_0\) that point-wise fix a 2-plane in 24, and we have observed that the resulting, \(g\)-twined multiplicity generating functions, for \(g \in G\), are vector-valued mock modular forms with a certain extra symmetry, relating the components labelled by \(\pm 1/2\) by complex conjugation.

**8 Mathieu moonshine**

In the previous sections we have seen that the orbifold theory described in Sect. 2 leads to infinite-dimensional \(G\)-modules underlying a set of vector-valued mock modular...
forms from its $\mathcal{N} = 4$ ($\mathcal{N} = 2$) structures for any subgroup $G$ of $Co_0$ fixing at least a 3-plane (2-plane) in $24$. In this section we will discuss a natural property of the vector-valued mock modular forms that distinguishes subgroups of $M_{24}$ from other 3-plane (2-plane) fixing subgroups. These considerations lead to mock modular Mathieu moonshine involving distinguished vector-valued mock modular forms of weight $1/2$.

Recall the celebrated genus zero condition of monstrous moonshine, which states that the monstrous McKay–Thompson series are Hauptmoduls with only a polar term $q^{-1}$ at the cusp represented by $i\infty$, and no poles at any other cusps. To be more precise, denote by $T_g(\tau) = \sum_{n > -1} q^n \psi_n^{(i)}$ the graded character of the moonshine module $V^{(i)} = \bigoplus_{n \geq -1} V_n^{(i)}$ of Frenkel–Lepowsky–Meurman [37]. Then $T_g(\tau)$ is a function invariant under the action of a particular $\Gamma_g < SL_2(\mathbb{H})$ (specified in [15]), such that

$$
\begin{align*}
(i) & \quad qT_g(\tau) = O(1) \text{ as } \tau \to i\infty, \\
(ii) & \quad T_g(\gamma \tau) = O(1) \text{ as } \tau \to i\infty \text{ whenever } \gamma \in SL_2(\mathbb{Z}) \text{ and } \gamma \infty \notin \Gamma_g \infty. 
\end{align*}
$$

(8.1)

Similarly, in Mathieu moonshine [35], it follows from the results of [7] that if $g \in M_{24}$ and $Z_g$ denotes the $g$-twined K3 elliptic genus then

$$
\begin{align*}
(i) & \quad Z_g(\tau, z) = c_g + y + y^{-1} \text{ as } \tau \to i\infty, \\
(ii) & \quad Z_{g|0,1}\gamma(\tau, z) = c_{g,\gamma} \text{ as } \tau \to i\infty \text{ whenever } \gamma \in SL_2(\mathbb{Z}) \text{ and } \gamma \infty \notin \Gamma_g \infty, 
\end{align*}
$$

(8.2)

(cf. (5.4)) for some $c_g, c_{g,\gamma} \in \mathbb{C}$. In other words, the $\tau \to i\infty$ limit of $Z_{g|0,1}\gamma$ is a $z$-independent constant whenever $\gamma$ is not in the invariance group $\Gamma_g$. (Note that $\Gamma_g$ is always a subgroup of $SL_2(\mathbb{Z})$ for $g \in M_{24}$).

A natural question is therefore: among the subgroups of $Co_0$ fixing 2- or 3-planes for which we have constructed a module in this work, for which of these do the associated modular objects satisfy a condition analogous to the preceding cases of moonshine described above? We will see presently that the Mathieu groups $M_{23}, \ M_{22}, \ M_{12}$ and $M_{11}$ are distinguished in our setting, in that the graded characters of their respective modules yield weight zero weak Jacobi forms satisfying the conditions

$$
\begin{align*}
(i) & \quad Z_g(\tau, z) = c_g + y^2 + y^{-2} \text{ as } \tau \to i\infty, \\
(ii) & \quad Z_{g|0,2}\gamma(\tau, z) = c_{g,\gamma} \text{ as } \tau \to i\infty \text{ whenever } \gamma \in SL_2(\mathbb{Z}) \text{ and } \gamma \infty \notin \Gamma_g \infty, 
\end{align*}
$$

(8.3)

for some $c_g, c_{g,\gamma} \in \mathbb{C}$. On the other hand, all the other groups mentioned in Sect. 4 contain elements $g$ for which the condition (ii) in (8.3) is not satisfied. Thus the conditions (8.3) single out the Mathieu groups as the sporadic simple subgroups of $Co_0$ with this moonshine property. The constructions we have presented in this paper provide concrete realizations of the underlying mock modular Mathieu moonshine modules.

Note that the conditions (8.3) impose restrictions on the degrees of the poles (if any) of the mock modular forms $h_{g\gamma}, \tilde{h}_g$ (cf. Sects. 6, 7) at all cusps. In fact, for the case that $G$ is a copy of $M_{22}$ or $M_{11}$ preserving $\mathcal{N} = 4$ supersymmetry, the corresponding mock modular forms $h_g$ only have poles at the infinite cusp. This property also holds for the mock modular forms attached to $M_{24}$ via $\mathcal{N} = 4$ decomposition of the twined K3 elliptic genera of Mathieu moonshine, satisfying (8.2), as was demonstrated in [7]. In more
physical terms, (8.2) and (8.3) can be interpreted as the condition that the elliptic genus of any cyclic orbifold of the theory receives no contributions from \( U(1) \)-charged ground states. To investigate the behaviour of \( Z_g \) at cusps other than \( i\infty \), we first note that for any positive integer \( N \),

\[
Z_g|_{\Omega_2} \left( \begin{array}{cc} 1 & 0 \\ N & 1 \end{array} \right) (\tau, z) = e \left( N \sum_{\ell=1}^{12} \frac{\rho_\ell^2}{2} \right) \sum_{i=1}^{4} \epsilon_i N (-1)^{i+1} \Theta_{i, N}(\tau, z),
\]

where

\[
\Theta_{i, N}(\tau, z) = \frac{\theta_i(\tau, 2z)}{\eta^{12}(\tau)} \prod_{k=2}^{12} e \left( \frac{\rho_\ell^2 N^2}{2} \tau \right) \theta_i(\tau, \rho_k + N \rho_k \tau),
\]

and \( \epsilon_{i, N} = \epsilon_i \) when \( 2|N \), and

\[
\begin{align*}
\epsilon_{1, N} &= -\epsilon_1 \\
\epsilon_{2, N} &= -\epsilon_3 = -1 \\
\epsilon_{3, N} &= -\epsilon_2 \\
\epsilon_{4, N} &= -\epsilon_4 = -1
\end{align*}
\]

otherwise. The above expressions can be derived from the transformation laws of Jacobi theta functions under \( SL_2(\mathbb{Z}) \).

Near the infinite cusp, \( \tau \to i\infty \), the different contributions have the following leading behaviour:

\[
\begin{align*}
\Theta_{1, N}(\tau, z) &= e \left( \frac{1}{2} + \sum_{k=1}^{12} \left( \frac{1}{2} - \rho_k \right) [N \rho_k] - \frac{\rho_k}{2} \right) d^{6,1}(\Pi_k)/2 (y - y^{-1}) \left[ 1 + O(q^{1/2}) \right] \\
\Theta_{2, N}(\tau, z) &= e \left( \sum_{k=1}^{12} -\rho_k [N \rho_k] - \frac{\rho_k}{2} \right) d^{6,1}(\Pi_k)/2 (y + y^{-1}) \left[ 1 + O(q^{1/2}) \right] \\
\Theta_{3, N}(\tau, z) &= e \left( -\sum_{k=1}^{12} \rho_k \left( \frac{1}{2} + N \rho_k \right) \right) d^{6,2}(\Pi_k)/2 (1 + q^{1/2} y^2 + y^{-2}) \\
&\quad \times \left[ 1 + O(q^{1/2}) \right] \\
\Theta_{4, N}(\tau, z) &= e \left( -\sum_{k=1}^{12} \left( \frac{1}{2} + \rho_k \right) \left( \frac{1}{2} + N \rho_k \right) \right) d^{6,2}(\Pi_k)/2 (1 - q^{1/2} (y^2 + y^{-2})) \\
&\quad \times \left[ 1 + O(q^{1/2}) \right]
\end{align*}
\]

with

\[
f_{N, 1}(\Pi_k) = -1 + \sum_{k=1}^{12} (N \rho_k - 1/2)^2 + [N \rho_k] (1 + [N \rho_k] - 2N \rho_k),
\]

(8.7)
where \(|x|\) denotes the largest integer that is not greater than \(x\).

Comparing with the second condition in (8.3), we see that it is satisfied for \(\gamma = \begin{pmatrix} 1 & 0 \\ N & 1 \end{pmatrix}\) if and only if the \(\Pi_g\) satisfies

\[
\tilde{f}_{N,2}(\Pi_g) > 0,
\]

together with

\[
\tilde{f}_{N,2}(\Pi_g) > -1, \quad \frac{\tilde{f}_{N,2}(\Pi_g)}{2} + \left| N \rho_k - N \rho_k \right| \geq 0
\]

for the case \(\varepsilon_3,\varepsilon_4,\varepsilon_N \varepsilon (\frac{1}{N} \sum_{k=1}^{12} \frac{1}{2} N \rho_k) = 1\), and

\[
\tilde{f}_{N,2}(\Pi_g) \geq 0
\]

for the case \(\varepsilon_3,\varepsilon_4,\varepsilon_N \varepsilon (\frac{1}{N} \sum_{k=1}^{12} \frac{1}{2} N \rho_k) = 0\).

Now we are left to check explicitly the condition (ii) in (8.3) for the various 2- and 3-plane preserving subgroups discussed in Sect. 4. First, recall that, for \(n\) a positive integer, each cusp of \(\Gamma_0(n)\) is represented by a rational number of the form \(u / v\) where \(u\) and \(v\) are coprime positive integers, \(v\) a divisor of \(n\), and \(u / v\) is equivalent \(u'/v'\) if and only if \(v = v'\), and \(u = u' \mod (v,v/v)\). (Note that the infinite cusp is also represented by \(1 / n\).) Via direct computation using the data of the eigenvalues of \(g \in Co_0\) acting on \(24\), we note that among all the groups we have considered in Sect. 4, the groups \(U_4(3), U_6(2)\) and \(Mcl\) all contain a conjugacy class with Frame shape \(\Pi_g = 3^9/1^3\), and \(HS\) has a conjugacy class with Frame shape \(\Pi_g = 5^5/1^1\). One can explicitly check that \(f_{1,1}(\Pi_g) = 0\) for these classes and hence the corresponding twining \(Z_{\Pi_g} \tilde{f} \left( \frac{1}{1} \right) (\tau, z)\) has a non-vanishing coefficient for \(q^0 y^1\) as \(\tau \to i \infty\). (Note that the cusp at \(\tau = 1\) is not equivalent to the cusp at \(i \infty\) in these cases.) This excludes the groups \(U_4(3), U_6(2), Mcl\) and \(HS\) as candidates for moonshine satisfying (8.3).

For the subgroups of \(M_{24}\), a simple analysis of the cusp representatives of \(\Gamma_g = \Gamma(o_g)\) shows that it is sufficient to verify (8.3) for \(\gamma = \begin{pmatrix} 1 & 0 \\ N & 1 \end{pmatrix}\) for all \(N|n\) and \(N < n\). For these cases, we explicitly verify that (8.9)–(8.11) are satisfied and hence the moonshine condition (8.3) is met.

We therefore conclude that we have established mock modular moonshine for all but the largest of the sporadic simple Mathieu groups, together with explicit constructions of the corresponding modules. Moreover, the corresponding twined graded characters are mock modular forms arising from Jacobi forms satisfying the distinguishing conditions (8.3), which we may recognise as furnishing a natural analogue of the powerful principal modulus property (a.k.a. genus zero property) of monstrous moonshine.

The reader will note that many of the numbers which occur as dimensions of irreducible representations of \(M_{23}\) also occur as dimensions of irreducible representations for \(M_{24}\). Indeed, looking at the Tables in “Appendix C”, one is tempted to guess that there is an alternative construction, or hidden symmetry in our model, which yields an \(M_{24}\) -module with the same graded dimensions. In fact, the procedure we have explained for computing twinings can be carried out for any element of \(M_{24}\), regarded as a subgroup
of \( \text{Co}_0 \) for any such element fixes a 2-space in \( \mathbf{24} \). However, there is no 2-space that is fixed by every element of a given copy of \( M_{24} \), and explicit computations reveal that any \( M_{24} \)-module structure on the module we have constructed would have to involve virtual representations. This indicates that there is no direct extension to \( M_{24} \) of the Mathieu moonshine modules we have considered here, despite the prominent role \( M_{24} \) plays in incorporating the different groups of moonshine in the current setting. Nevertheless, there is a certain modification of our method for which \( M_{24} \) is now known to play a leading role. We refer the reader to the next, and final section for a description of this.

9 Discussion

In this paper we have demonstrated that, starting with the free field \( \text{Co}_0 \) module of \([24]\), one can construct explicit examples of modules for various subgroups \( G \subset \text{Co}_0 \) which underlie certain mock modular forms. In particular, subgroups which preserve a 3-plane (respectively 2-plane) in the \( \mathbf{24} \) give rise to \( \mathcal{N} = 4 \) (\( \mathcal{N} = 2 \)) modules with \( G \) symmetry. This gives completely explicit examples of mock modular moonshine for the smaller Mathieu groups, where the modules are known, and where the twining functions are distinguished in a manner directly similar to Mathieu moonshine. Other examples, including modules for the sporadic groups \( \text{McL} \) and \( \text{HS} \), are also described.

There are several future directions. We considered here the \( \mathcal{N} = 2 \) and \( \mathcal{N} = 4 \) extended chiral algebras, and the subgroups of \( \text{Co}_0 \) that they preserve. Other extended chiral algebras may also yield interesting results. For instance, supersymmetric sigma models with target a Spin(7) manifold give rise to an extended chiral algebra \([58]\), whose representations were studied in \([45]\). It is an extension of the \( \mathcal{N} = 1 \) superconformal algebra where instead of adding a \( U(1) \) current (which extends the theory to an \( \mathcal{N} = 2 \) superconformal theory), one chooses an additional Ising factor. Conjectural characters for the unitary, irreducible representations of this algebra were worked out in \([2]\), where it was shown that there is a suggestive relation between the decomposition of the elliptic genus of a Spin(7) manifold into these characters and irreducible representations of finite groups. This connection was made precise in \([12]\), where it was shown that the same \( c = 12 \) theory can be viewed as an SCFT with extended \( \mathcal{N} = 1 \) symmetry, and thus yields theories with global symmetry groups \( M_{24}, \text{Co}_2, \text{and Co}_3 \). The partition function twined by these symmetries, when decomposed into characters of the Spin(7) algebra, gives rise to two-component vector-valued mock modular forms encoding infinite-dimensional modules for the corresponding sporadic groups.

The motivation that led, eventually, to the present study was actually to find connections between geometrical target manifolds associated to \( c = 12 \) conformal field theories, and sporadic groups. The elliptic genera of Calabi-Yau fourfolds were computed in \([54]\), for instance; their structure is reminiscent of some of the modules we have seen here, and we intend to further explore and describe some of these connections in a future publication. Likewise, hyperkähler fourfolds, as well as the Spin(7) manifolds mentioned above, provide a wide class of geometries where an analogue of the connections between \( M_{24} \) and K3 may be sought.

Last but not least, there are suggestive connections between the trace functions in moonshine modules, and certain special properties of the underlying conformal field theory. Both the CFT appearing in monstrous moonshine and the \( \text{Co}_0 \) module that
played a starring role in this paper appear to play special roles also in AdS\(_3\) quantum gravity, where they are candidates for CFT duals to pure (super)gravity [62]. The genus zero property of the twining functions in monstrous moonshine can be reformulated as a condition that these class functions should be expressed as Rademacher sums based on a fixed polar part [7, 29]; this latter description then applies uniformly to monstrous moonshine.

In this paper we demonstrate that a similar criterion also applies to our mock modular Mathieu moonshines. In particular, we have shown that the Jacobi forms relevant for Mathieu moonshine display a specific asymptotic behaviour near non-infinite cusps, which, in physical terms, can be interpreted as a condition on orbifolds of the theory. Pursuing a deeper understanding of this property constitutes an enticing direction for the future.

10 Endnote

\(^a\)See however the recent work [26] which constructs the super vertex operator algebra underlying the \(X = E_8^8\) case of umbral moonshine.

\(^b\)The observation that the decomposition into \(\mathcal{N} = 4\) characters of (a multiple of) the function \(Z(\tau, z)\) returns positive integers that are suggestive of representations of the Mathieu group \(M_{22}\) was first communicated privately by Jeff Harvey to J.D. in 2010.

Appendix A: Jacobi theta functions

We define the Jacobi theta functions \(\theta_i(\tau, z)\) as follows for \(q = e(\tau)\) and \(y = e(z)\):

\[
\theta_1(\tau, z) = -iq^{1/8}y^{1/2}\prod_{n=1}^{\infty}(1 - q^n)(1 - yq^n)(1 - y^{-1}q^{n-1}), \tag{9.1}
\]

\[
\theta_2(\tau, z) = q^{1/8}y^{1/2}\prod_{n=1}^{\infty}(1 - q^n)(1 + yq^n)(1 + y^{-1}q^{n-1}), \tag{9.2}
\]
\[ \theta_3(\tau, z) = \prod_{n=1}^{\infty} (1 - q^n)(1 + y q^{n-1/2})(1 + y^{-1} q^{n-1/2}), \quad (9.3) \]
\[ \theta_4(\tau, z) = \prod_{n=1}^{\infty} (1 - q^n)(1 - y q^{n-1/2})(1 - y^{-1} q^{n-1/2}). \quad (9.4) \]

They transform in the following way under the group \( SL_2(\mathbb{Z}) \ltimes \mathbb{Z}^2 \).

\[ \theta_1(\tau, z) = i \alpha^{-1}(\tau, z) \theta_1 \left( \frac{1}{\tau}, \frac{z}{\tau} \right) = e(-1/8) \theta_1(\tau + 1, z) \]
\[ = (-1)^{\lambda + \mu} e^{\left( \frac{1}{2}(\lambda^2 \tau + 2 \lambda z) \right)} \theta_1(\tau, z + \tau \lambda + \mu), \]
\[ \theta_2(\tau, z) = \alpha^{-1}(\tau, z) \theta_3 \left( \frac{1}{\tau}, \frac{z}{\tau} \right) = e(-1/8) \theta_2(\tau + 1, z) \]
\[ = (-1)^{\lambda} e^{\left( \frac{1}{2}(\lambda^2 \tau + 2 \lambda z) \right)} \theta_2(\tau, z + \tau \lambda + \mu), \]
\[ \theta_3(\tau, z) = \alpha^{-1}(\tau, z) \theta_2 \left( \frac{1}{\tau}, \frac{z}{\tau} \right) = \theta_4(\tau + 1, z) \]
\[ = e^{\left( \frac{1}{2}(\lambda^2 \tau + 2 \lambda z) \right)} \theta_3(\tau, z + \tau \lambda + \mu), \]
\[ \theta_4(\tau, z) = \alpha^{-1}(\tau, z) \theta_1 \left( \frac{1}{\tau}, \frac{z}{\tau} \right) = \theta_3(\tau + 1, z) \]
\[ = (-1)^{\lambda} e^{\left( \frac{1}{2}(\lambda^2 \tau + 2 \lambda z) \right)} \theta_4(\tau, z + \tau \lambda + \mu). \quad (9.5) \]

Here \( \alpha(\tau, z) = \sqrt{-i} e^{\frac{z^2}{4\pi}}, \) and \( \lambda, \mu \in \mathbb{Z}. \)

The weight four Eisenstein series \( E_4 \) can be written in terms of the Jacobi theta functions as

\[ E_4(\tau) = \frac{1}{2} \left( \theta_2(\tau, 0)^8 + \theta_3(\tau, 0)^8 + \theta_4(\tau, 0)^8 \right). \quad (9.6) \]

### Appendix C: Coefficient tables

See Tables 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28.

**Table 15** The twined series for $M_{22}$. The table shows the Fourier coefficients multiplying $q^{-D/12}$ in the $q$-expansion of the function $h_{g,1}(\tau)$
