ABSTRACT

This paper presents the University of Amsterdam’s participation in the TREC 2016 Contextual Suggestion Track. In this research, we have studied a personalized neural document language modeling and a neural category preference modeling for contextual suggestion using available endorsements in TREC 2016 contextual suggestion track phase 2 requests. Specifically, our main aim is to answer the questions: How to effectively model users’ profiles using the suggestions’ endorsements as an additional data? How effective is using word embeddings to boost terms’ weights relevant to the given endorsements? How to model users’ attraction-category preferences? How effective is using deep neural networks to learn users’ category preferences in contextual suggestion task? Our main findings are the following: First, the neural personalized document based user profiling using word embeddings improves the baseline content-based filtering approach based on all the common IR measures including TREC 2016 Contextual Suggestion official metric (NDCG@5). Second, neural users’ category preference modeling beats both baseline content-based filtering and the user profiling model using word-embeddings in terms of all the common IR measures.

Moreover, TREC 2016 contextual suggestion track organizers released related tags of each attraction in the qrels file. These endorsements in a way classify suggestions, which is potentially good source of information to improve users’ preference modeling. In this paper, we mainly focus on how to build and use the tag preference model in order to build contextual suggestion systems.

In TREC 2016, contextual suggestion track organizers distributed the TREC contextual suggestion web corpus, which is a web archive of the released TREC Contextual Suggestion data collection being used in both TREC 2015 and 2016 [2, 9]. In this study, we have indexed and used the released corpus as a dataset in our experiments.

TREC 2016 contextual suggestion allowed participants to participate in the contextual suggestion phase 1 or phase 2 experiments. In the phase 1 experiment, participants return a list of attraction IDs from the TREC 2016 contextual suggestion collection, but in the phase 2 experiment, participants were allowed to use the open web to retrieve suggestion candidates. All of them used the webpages of the aggregator websites such as Yelp, Google Places, Foursquare and TripAdvisor. A considerable fraction of the participants used category of suggestion candidates that is available in the Yelp website. In that track, the given context had geographical and temporal aspects.

In the TREC 2013 and TREC 2014, the participants could use either the open web or the ClueWeb12 dataset, but there were only seven submitted runs out of 34 in 2013 and 6.
Algorithm 1 Estimating a Personalized Document LM

1: procedure PDLM\((d, TG_u(d))\)
2: for each \(t \in \mathcal{D}\) do
3: \(P(t|\theta_d) = \frac{tf(t,d)}{|d|}\)
4: \(P(t|\theta_u) = \frac{1}{|TG_u(d)|} \sum_{tg \in TG_u(d)} P(t|\theta_d)P(t|tg)\)
5: end for
6: end procedure

Algorithm 2 Estimating a User Model

Require:
- \(D_u = \{d_1, d_2, ..., d_M\}\) Document preference of user \(u\).
- \(V_u = \{t_1, t_2, ..., t_M\}\) User vocabulary.

Ensure:
- \(\theta_u\) User Model.

1: for each \(d \in D_u\) do
2: \(\theta_{d_u} \leftarrow PDLM(d, TG_u(d))\)
3: end for
4: for each \(t \in V_u\) do
5: for each \(d \in D_u\) do
6: \(P(t|\theta_u) = \frac{1}{|D_u|} \sum_{d \in D_u} P(t|\theta_u)\)
7: end for
8: end for

where \(tf(t,d)\) is a frequency of term \(t\) in the document \(d\), and \(|d|\) is a document length.

Then, we estimate the personalized document model \(\theta_{d_u}\) using tags \(TG_u(d)\) as follow:

\[
P(t|\theta_{d_u}) = \frac{1}{|TG_u(d)|} \sum_{tg \in TG_u(d)} P(t|\theta_d)P(t|tg) \tag{2}
\]

where \(P(t|\theta_d)\) is the probability of term in a document as described in Eq.1, \(P(t|tg)\) is a probability of selecting a term \(t\) given a tag \(tg\), and \(|TG_u(d)|\) number of tag assigned to the document \(d\) by a user \(u\).

The probability \(P(t|tg)\) is computed using the cosine similarities between the two embedded vectors corresponding to term \(t\) and tag \(tg\) as follow:

\[
P(t|tg) = \text{sim}(t, tg) \tag{3}
\]

3.1 User Profiling Using Word Embeddings

This section studies how to effectively model users’ profiles to be used in the content based filtering systems, aiming to answer our first research question: How to effectively model users’ profiles using neural language modeling?

3.1.1 Personalized Document Language Model

In this part, we present how to personalize a document model using user tags. The goal is to estimate a best personalized term distribution for the document according to the tags assigned by a user.

Our approach is shown in Algorithm 4. Given a document \(d = \{t_1, t_2, ..., t_n\}\) and his related tags \(TG_u(d) = \{tg_1, tg_2, ..., tg_m\}\) assigned by a user \(u\). We first estimate a document model \(\theta_d\) as first estimation using maximum likelihood as follow:

\[
P(t|\theta_d) = \frac{tf(t,d)}{|d|} \tag{1}
\]
In order to model the contextual suggestion, we cast the context-aware recommendation problem to a binary classification problem, in which relevant suggestions in the users’ profiles are labeled 1 and irrelevant ones labeled 0. In this way, we try to learn a model to predict relevant suggestion candidates to the given user profile and the context by the help of users’ category preferences. Then, relevance probability of suggestion candidates to the user and context pairs will be used to rank the phase 2 suggestion candidates.

In order to learn the model, a set of features that represent how relevant is each suggestion to each category defined. To this aim, we have created a profile of each given category in the TREC 2016 contextual suggestion requests. Then, we have considered content-based relevance of each category profile to the suggestion as a feature in our both train and test sets. We have found 123 unique categories in the phase 2 requests in total. Therefore, we have defined KL-divergences of 123 category profiles to a suggestion profile as 123 different features for the relevance estimation of the suggestion based on the category preferences.

In order to learn a user preference model, we have used a deep neural network with 4 hidden layers having 478 units. To learn an effective model and avoid over-fitting, we have used a dropout feedforward neural network. Let \( l \in \{1, 2, 3, 4\} \) be the index of the hidden layers of the network. Let \( z^{(l)} \) be the vector of input to layer \( l \) and \( y^{(l)} \) be the vector of outputs from layer \( l \). We have modeled the dropout neural network as follows for any hidden unit \( i \) and \( l \in \{0, 1, 2, 3\} \):

\[
\begin{align*}
   r^{(l)} & \sim \text{Bernoulli}(p), \\
   \tilde{y}^{(l)} & = r^{(l)} \ast y^{(l)}, \\
   z^{(l+1)} & = w^{(l+1)} \ast \tilde{y}^{(l)} + b^{(l+1)}, \\
   y^{(l+1)} & = f(z^{(l+1)}),
\end{align*}
\]

where \( r^{(l)} \) is a vector of independent Bernoulli random variables having probability \( p \) of being 1, \( \tilde{y}^{(l)} \) denotes thinned outputs created by multiplying a sample of \( r^{(l)} \) vector by outputs of layer \( l \) (i.e., \( y^{(l)} \)) and used as input for the next layer \( l + 1 \), \( w^{(l)} \) is weights at layer \( l \), \( b^{(l)} \) is biases at layer \( l \), and \( f \) is an activation function, which is rectified linear units (ReLUs) in our setup. This process is done at each layer.

As earlier research on neural networks reported \( p = 0.5 \) as a close to optimal value for a wide range of networks in different applications \([11]\), we have also used \( p = 0.5 \) in our dropout network.

In the learning phase using phase 2 profiles of each request, the derivatives of the loss function are back-propagated through the dropout network. We have used the stochastic gradient descent (SGD) algorithm with mini batches to train the dropout network. The adaptive gradient algorithm (AdaGrad) \([3]\) is used to adjust the learning rates.

For the classification purpose and having probabilities as outputs, we have used Logistic classifier in the last layer. We use variable \( c \in \{0, 1\} \) to show relevance of a suggestion to the given user in a context. Specifically, \( P_b(c = 1|u, c, s) \) is the relevance score of the suggestion \( s \) to the user \( u \) and context \( c \), in which \( \theta \) is unknown parameters that are learned using maximum likelihood estimation (MLE) based on the train set, which consists of the users’ preferences available in the profile of each request.

Given the relevance judgments \( r \) of each suggestion \( s_k \) to a user \( u_i \) and context \( c_j \) in the users’ profiles available at each requests, the likelihood \( L \) of the train set is as follows:

\[
L = \prod_{i=1}^{\|U\|} \prod_{j=1}^{\|C\|} \prod_{k=1}^{\|S\|} P_b(c = 1|u_i, c_j, s_k)^r P_b(c = 0|u_i, c_j, s_k)^{1-r},
\]

in which we assume relevance judgments \( r \) are generated independently. We model \( P_b(c = 1|u_i, c_j, s_k) \) by logistic function on a linear combination of inputs from the last hidden layer units’ outputs. Then, the unknown parameters \( \theta \) are optimized by maximizing the following log likelihood function:

\[
\theta^* = \underset{\theta}{\text{argmax}} \sum_{i=1}^{\|U\|} \sum_{j=1}^{\|C\|} \sum_{k=1}^{\|S\|} r \log P_b(c = 1|u_i, c_j, s_k) + (1-r) \log P_b(c = 0|u_i, c_j, s_k).
\]

## 4. RESULTS

In this section, the result of the two approaches detailed in Section 3 is discussed. These results are based on the official TREC 2016 Contextual Suggestion track qrels.

In order to evaluate our proposed models, we have implemented a content-based filtering baseline using standard language model to model users’ profiles, and we have used KL-divergence to estimate relevance of the suggestion candidate to the user profile. Table 1 shows our submissions results against the content-based filtering baseline.

As it is shown in Table 1 both the proposed neural approaches beat the baseline in terms of all the common IR measures. The category of the attractions proves to be very useful to include in the contextual suggestion systems, explaining why the “UAmsterdamDL” approach performed better than the two others phase 2 runs.

## 5. CONCLUSION

In this paper, we studied contextual suggestion problem through neural user profiling and neural category preference modeling by the help of suggestions’ endorsements. According to the phase 2 results of the TREC 2016 contextual suggestion track, using word embeddings to boost terms’ weights related to suggestions’ endorsements improves baseline content-based filtering approach in the contextual suggestion problem based on all common IR measures. Moreover, phase 2 results show that neural category preference

modeling of the users can lead to even better results than the other tested user modeling approaches in contextual suggestion task. Specifically, the contextual suggestion submitted run based on neural category preference modeling performs better than our user profiling based submission and the content-based filtering baseline in terms of all the common IR measures including the TREC contextual suggestion official evaluation metric (NDCG@5). As a future work, we continue to work on users’ preference modeling using category profiles created based on word embeddings.
