Our paper [1] included a calculation of the parameter $f_N$, the coupling between the Higgs boson and nucleons. Because of an unfortunate bug in the code used for examining the possible values of $f_N$, the value that we originally quoted, $0.345 \pm 0.016$, was incorrect.

Figure 1 is an updated version of Fig. 5 from the original paper, showing the corrected distributions of related quantities. In the Gaussian case, we find $f_N = 0.30 \pm 0.01$ at the formal 1-sigma (68.3% C.L.) level. In the top-hat case, we find the same mean value, but the $f_N$ distribution is broader and not Gaussian. We roughly estimate that $f_N = 0.30 \pm 0.03$ in this case. Statistically combining the two approaches yields an uncertainty of about $\pm 0.015$.

This correction does not affect our conclusions in a qualitative sense, but it does very slightly weaken the limits we showed from direct detection. The version of the paper in the arXiv e-print archive has been updated to use the correct value of $f_N$, including all plots featuring limits or projections from direct detection.

We also take this opportunity to point out that we misquoted the Cherenkov Telescope Array observing time assumed in the original paper; it should have been 200 h, not 500 h. The arXiv e-print version contains the corrected value.
