An efficient catalytic system for the C–H olefination of arenes with different allylic substrates is reported. The catalytic system is based on Pd(OAc) 2 and a readily accessible bidentate S,O-ligand. The methodology shows high activity with a wide range of arenes, including bulky and, electron-rich and -poor arenes. The applicability of this catalyst is demonstrated in the late-stage functionalization of the complex molecule O-methylestrone.

In recent years, metal-catalyzed C–H functionalization reactions have become an attractive strategy to introduce complexity to organic molecules since no pre-functionalization of the starting materials is required. Many elegant and efficient methodologies have been described for the direct functionalization of C–H bonds, but the vast majority of these examples require the presence of a directing group to enhance the reactivity and selectivity of the process. Reports of the direct C–H functionalization of simple arenes, without a directing group, are still scarce. An attractive alternative to the use of directing groups is the use of suitable ligands capable of promoting these transformations.

We recently reported a new type of bidentate S,O-ligand, namely 2-i-propyl-2-(phenylthio) acetic acid (L1), that enables the non-directed Pd-catalyzed C–H olefination of arenes with activated olefins. The methodology is scalable and applicable to the late-stage functionalization of complex molecules. Although our standard reaction conditions (Pd(OAc) 2/L1; PhCO 2Bu; AcOH) provided poor yields and did not accelerate the reaction with non-activated alkenes, the use of AgOAc in DCE was observed to have a beneficial effect in promoting the olefination of benzene with allylbenezene when L1 was present in the reaction mixture (Scheme 1).

Inspired by this preliminary result, we decided to explore the scope of the new catalytic system in the C–H olefination of arenes with allylic substrates, including allyl acetate and N-allylphthalimide. Herein, we report the S,O-ligand promoted palladium(II)-catalyzed C–H olefination of arenes with allylic substrates. The new methodology is suitable for a wide range of arenes and allylic substrates and its applicability is demonstrated in the late-stage functionalization of a complex molecule.
Entries 4–8). Other arenes with different electronic properties, such as anisole, 4-chloroanisole, 4-methoxyanisole and 1,3,5-trifluorobenzene were also evaluated in the reaction with allyl acetate. In all cases, the allylated products were obtained in good isolated yields (40–88%, Entries 9–12). In addition, we tested the reaction of N-allylphthalimide with mesitylene and 1,3,5-trimethoxybenzene. In both cases, the allylated products were isolated in good yields (73% and 61%, respectively, Entries 13–14). Importantly, in all cases, the reaction was accelerated in the presence of L1 and low yields were obtained without the ligand after 20–24 h (Table 1, Entries 1–14). It is worth highlighting the effect of the ligand L1 in

the reactivity with the bulky mesitylene. The reaction of mesitylene with allyl acetate or N-allylphthalimide in the absence of L1 proceeded with conversions lower than 20%. In contrast, the allylated products 9 and 14 were obtained in 67% and 73% isolated yield, respectively, in the presence of L1 (Entries 8 and 13). In general, the new catalytic system promoted the allylation of a wide variety of arenes including bulky, electron-rich and electron-poor arenes, providing a broader substrate scope than the majority of the reported examples.7–9 With respect to other arenes, we found that the reaction of different dichlorobenzene derivatives provided the corresponding allylated products in low yields, with and without L1. Regarding the site-selectivity of the process, the allylation reaction takes place, preferentially, at the most electron-rich position in the arene (see a/b or o/m/p values in Table 1). Similar behaviour was observed in our previous work using activated olefins.6 Concerning the selectivity of β-hydride elimination in the reaction with allylbenzene, a c.a. 1:1 mixture of isomers was observed (Entries 1–3). For the olefination reactions with allyl acetate or N-allylphthalimide, more complex mixtures of products can be formed. However, in all of the examples evaluated, we observed only the products from internal carbopalladation (Entries 4–14). After the carbopalladation step, β-OAc [or β-[NPhth]] elimination or β-hydride elimination can take place. However, under our reaction conditions, we did not detect the products derived from β-OAc [or β-[NPhth]] elimination. Furthermore, with respect to the β-hydride elimination pathway, although two possible products can be formed, we observed mainly the products from the β-hydride elimination that leads to the double bond in conjugation with the arene. This high regioselectivity has been previously attributed to chelation between the O and the Pd atom.7,8a,b,c This chelation impedes rotation around the C–C bond and therefore, hinders the syn relationship between the Pd and Hα (Scheme 2).

To this general trend, we found that the reaction with mesitylene and 1,3,5-trifluorobenzene afforded the allylated products 9, 13 and 14 with moderate regioselectivity (71/29 for mesitylene and 62/38 for 1,3,5-trifluorobenzene; Entries 8, 12 and 13, respectively). In addition, some isomerization of double bond to the Z isomer occurred in the reaction of these arenes with allyl acetate (Entries 8 and 12). The low regioselectivity observed can be explained by the steric hindrance of the arene, which hampers rotation around the C–C bond, disfavouring the syn relationship between the Pd and Hβ.10

Reagents and conditions: arene (33 or 66 equiv.), olefin (1.0 equiv.), Pd(OAc)2/S,O-Ligand (10 mol%), AgOAc (1.5 equiv.), DCE, 80–100 °C, 20–24 h.

Scheme 2. Source of the high observed regioselectivity.

Scheme 3. Late-stage C–H olefination of Estrone.
To further prove the generality of the new catalytic system, we applied the new developed methodology to the late-stage functionalization of a complex molecule (Scheme 3). The reaction of O-methylestrone (1 equiv.) with allyl acetate (1.5 equiv.) and Pd (OAc)₂ (10 mol%) provided the desired product in only 10% ¹H-NMR yield. To our delight, the same reaction in the presence of L₁ furnished the olefinated product 16 in 55% isolated yield as a mixture of ortho-olefinated isomers (a:b = 60:40).

In summary, the combination of Pd(OAc)₂ and the bidentate S, O-ligand L₁, was found to promote the C–H olefination of arenes with different allyl substrates, providing the desired allylated products in good yields. This transformation tolerates a wide range of arenes, including bulky, electron-rich and electron-poor arenes. The olefination reaction occurs preferentially at the most electron-rich position of the arene. Regarding the regioselectivity of the j-hydride elimination, mixtures of isomers were obtained in the reaction with allyl benzene and mainly one isomer in the reaction with allyl acetate and N-allyphthalimide; these results are in line with the general outcome of the Heck reaction. The applicability of the new catalytic system has been demonstrated in the late-stage functionalization of O-methylestrone.

7. The exact role of Ag(I) salts in this type of reaction is unclear but it has been proposed that can play a significant role to promote j-hydride elimination: Pan M, Yu M, Chen W. Ning J. Chem Asian J. 2010;5:1090–1093.

10. Another explanation for the low regioselectivity observed with mesitylene and 1,3,5-trifluorobenzene is that the ortho substitution prevents coplanarity of the π-system, making the conjugated isomer less stable.
