Chapter 4  Concept-guided development of technology use in ‘traditional’ and ‘innovative’ schools: quantitative and qualitative differences in technology integration

Introduction

An increasing body of studies indicates that digital technology has the potential to improve learning processes (cf. Archer, Savage, Sanghera-Sidhu, Wood, Gottardo, & Chen, 2014; Cheung & Slavin, 2012; Cheung & Slavin, 2013; Lemke, Coughlin, & Reifsnider, 2009). Well integrated use of technology in classroom practice is therefore by many considered desirable and is being advocated by many national governments (cf. Lewin & McNichol, 2015). In the literature a considerable amount of attention is paid to factors that either impede or promote adoption and integration of technology. The fit between the proposed technology use and the school’s educational concept is considered to be one of the factors that promote the integration of technology (Zhao, Pugh, Sheldon, & Byers, 2002; Niederhauser & Stoddart, 2001). Concept-guided development of technology, in which school teams develop and implement forms of technology use in line with the school’s educational concept, is a pedagogy-driven approach that aims to promote this fit and is therefore expected to promote the integration of technology that can enhance learning. Previous studies (de Koster, Kuiper, & Volman, 2012; de Koster, Volman, & Kuiper, 2013) have shown that schools with either a ‘traditional’ or an ‘innovative’ educational concept that developed their use of technology in a concept-guided way, realised clearly distinguishable types of technology use, aimed at supporting various types of teaching and learning. One of these previous studies (de Koster, Kuiper, & Volman, 2012) suggested there were

\[\text{de Koster, S., Volman, M., & Kuiper, E. (in revision). Concept-guided development of technology use in ‘traditional’ and ‘innovative’ schools: quantitative and qualitative differences in technology integration.}\]
differences in the ease with which the developed technology use could be integrated into the classroom. In this present study we investigated how the integration of the developed technology use into the different school types’ classroom practices can be characterised in quantitative and qualitative terms.

Background

Over the past 25 years a body of literature has developed that focuses on the integration of technology in education. In this literature we find a shift from a strong focus on the technology and its opportunities for teaching and learning to a focus on pedagogical desirabilities and the ways in which certain technologies can support these (Ertmer & Ottenbreit-Leftwich, 2013; Kampylis et al., 2013; Lewin & McNichol, 2015; Mor & Mogilevsky, 2013). This study clearly has the latter focus, being concerned with the integration of technology that has been identified by the teachers involved as providing a possible support for the teaching and learning that they aim for.

Promoting the integration of technology in educational practice

From the literature a number of conditions that promote successful integration of technology becomes apparent. A condition that is receiving growing attention is the fit between technology use and the educational concept underpinning these practices. Zhao, Pugh, Sheldon and Byers (2002) describe this in terms of the distance between the technology innovation (i.e. the intended development of the school’s use of technology) on the one hand, and the school’s educational culture and practice on the other hand. The shorter this distance, the better chances are for successful technology integration. This is consistent with findings indicating that how and with what learning effects technology resources are used, depends on how well they fit in with the established patterns of activity (Tolmie, 2001). Similarly, Niederhauser and Stoddart (2001) found that teachers are inclined to apply technology in a manner that is consistent with their personal perspectives about curriculum and instructional practice. This all seems to imply that if use of technology is developed to fit the school’s
educational concept, the chances of the technology becoming integrated into the school’s classroom practices are increased. Consistent with these findings a concept-guided approach to developing technology use has been proposed as a way to help schools integrate technology into their teaching and learning, where and when appropriate, by taking the school’s educational concept as the main starting point for developing its technology use (de Koster, Kuiper, & Volman, 2012).

**Defining technology integration**

Reviews of the literature on technology integration indicate that there is no unequivocal interpretation of the term technology integration (e.g. Hew & Brush, 2007; Vanderlinde, 2011). An often used indicator for technology integration is the quantity of use, like the number of computers available to students or the frequency with which technology is used, generally associating higher frequencies of use with higher levels of integration (e.g. Mueller, Wood, Willoughby, Ross & Specht, 2008; Tondeur, Hermans, van Braak & Valcke, 2008). Yet caution is due, as a comprehensive comparative PISA study (OECD, 2015) shows that although moderate frequencies of computer use at school can improve learning outcomes, very high frequencies of use appear to lead to considerably lower learning outcomes. So a high frequency of technology use in itself is not what schools should strive for. On the other hand we find studies that focus instead on the pedagogies that are being supported with technology. Many of these studies imply that technology can only be considered ‘integrated’ when it supports a specific type of teaching and learning. One example is the frequently cited five stage model of Sandholtz, Ringstaff and Dwyer (1997), which suggests that the highest stage of technology integration is only found in a context of innovative, constructivist teaching and learning (Mueller et al., 2008). Likewise Lim (2007) characterises effective technology integration in terms of teachers using technology to develop students’ thinking skills. In these studies the ultimate goal of integrating technology seems to be a use of technology that supports one specific type of pedagogy. A concept-guided approach to development of technology use however calls for a more neutral qualitative definition that gives room to a variety of pedagogies (‘educational concepts’) that can
be supported by integrated technology use. We propose that when taking a concept-guided approach our definition of technology integration should encompass the perceptions of the teachers who carry out these pedagogies in their everyday classroom practices. The question whether technology is successfully integrated into a school’s classroom practice thus translates into: do the teachers involved perceive the technology as having become an integral part of their practices?

This study

This study was performed in the context of a project in which five primary schools in the Netherlands developed technology-enhanced learning arrangements in a concept-guided way in the course of two school years (de Koster, Kuiper, & Volman, 2012). The schools participating in this project had an educational concept that was either labelled as ‘traditional’, which refers to a fixed curriculum and a strongly teacher-directed approach, or as ‘innovative’, indicating a more open curriculum and a student-centred approach. At each school a team of teachers was supported in designing and implementing up to four technology-supported learning arrangements of their own choosing. As the quantity of technology use is widely used and accepted as an indicator of technology integration we deemed it appropriate to include this aspect of integration in our study. Yet, befitting the concept-guided approach and the role of the teacher as the ‘embodiment’ of the school concept in the classroom, we propose to add to this the teacher’s perspective: How do the teachers who work with the technology appreciate it as a tool in their classroom practice? From this viewpoint the level of technology integration that can be achieved does not by definition depend on the school’s educational concept, as is suggested by the five stage model of Sandholtz, Ringstaff and Dwyer (1997) and similar theories, but rather depends on how well the technology use fits into the classroom practice. However, a previous study (de Koster, Kuiper, & Volman, 2012) did show that the ‘traditional’ schools developed less complex use of technology that was more easily implemented, while the ‘innovative’ schools designed rather complex use of technology, which seemed to hinder its implementation. These findings suggest that concept-guided development of technology use might lead to
concept-specific differences in the achieved levels of technology integration, possibly both in quantitative and in qualitative terms. This suggestion led to the main research question for this study:

*How can the achieved integration of technology in ‘traditional’ and ‘innovative’ schools that develop their use of technology in a concept-guided way be characterised in quantitative and qualitative terms?*

In order to answer this main question we formulated the following sub questions:

1. How can the achieved technology integration in these schools be characterised in quantitative terms?
2. How can the achieved technology integration in these schools be characterised in qualitative terms?
3. What differences can be found between the school types with regard to the quantitative and qualitative characteristics of technology integration?

**Method**

**Context of this study**

The study was conducted in the context of a project of concept-guided development of technology use in the Netherlands in which five primary schools participated. During the project a team of teachers at each school designed, developed and realised up to four technology-enhanced learning arrangements over the course of two school years. A learning arrangement would consist of a lesson plan, including learning goals, tools and activities, and could concern any school subject. Learning arrangements could entail anything from the use of ‘drill-and-practice’ software to the use of a wide range of technological tools to support a variety of learning activities in an enquiry-based project. Teachers participated on a voluntary basis and were given limited compensation of the time they invested in the project. The teachers were coached by educational counsellors from an external organisation. The educational counsellors helped the teachers reflect on their school’s educational concept and their school’s ambitions for
intensifying its use of technology in line with this concept. Based on this reflection the learning arrangements were designed as the teachers saw best fit. This procedure was expected to promote the fit between the school’s concept and the resulting use of technology. The teacher-as-designer approach, with an active, voluntary role for the participating teachers, was expected to favourably affect the implementation and integration of the designed learning arrangements by installing a sense of ownership in the teachers (Handelzalts, 2009; Maher, 1987). The researchers were not involved in the development of the learning arrangements.

Participants and setting

The five primary schools in this study were labelled as either ‘traditional’ (indicated as the Princess Amalia School and the Alma Mater School) or ‘innovative’ (indicated as the Beehive School, the Queen Beatrix School and the Beech Grove School). These labels were based on a general impression of the schools, extracted from interviews with stakeholders at each school at the start of the project, and verified by the researchers during the first year of the project. The teaching and learning practices at all participating schools met the standards of the Dutch Inspectorate of Education. At each school two or more teachers participated over a period of two school years. The grade levels of their classes varied from second to sixth grade.

In the ‘traditional’ schools educational goals are largely pursued through the use of teaching and learning materials with a more or less fixed content. Most instruction is given as direct whole-class instruction. After instruction, pupils mostly work individually or in pairs on assignments or exercises directly linked to the textbook content and remedial instruction is given in smaller groups, informed by test results. The three ‘innovative’ schools in this study intend to make learning attractive and engaging for pupils, for instance by giving them more control over their learning process and by using inquiry learning activities. Science and social sciences are taught in multidisciplinary projects revolving around a certain theme. Subject matter is partly, in one school mainly, taught in the form of workshops. Classes are multi-aged, in order to give pupils the opportunity to learn with and from each other. Standard teaching and
learning materials are mainly used as a general source of content and exercises at these schools.

**Instruments and data collection**

For this multiple case study (Yin, 2009) we operationalised technology integration both in quantitative and in qualitative terms. The quantitative character of the achieved technology integration (sub question 1) was captured through summarizing the number or different tools that were used in the learning arrangements and how many computers were available per class, based on data from embedded case studies (Yin, 2009) of each learning arrangement that was carried out. We obtained these data through classroom observations (mostly videotaped), individual interviews with teachers, and logs and registration forms filled in by teachers and pupils during the realisation of the learning arrangements. The data were gathered by two teams of researchers from different research institutes, one team investigating two schools, the other three. The descriptions of the learning arrangements based on the collected data were verified by the teachers involved. For the qualitative character of the achieved technology integration (sub question 2) we looked at how the teachers themselves perceived and valued the developed technology use in their schools. This was determined through analysis of semi-structured focus group interviews from an overall study of the project. The focus group interviews were held with the involved teams of teachers at each school, at the beginning of the first year (before the learning arrangements were realised, interview 1), at the end of the first year (one or two learning arrangements realised, interview 2), and at the end of the second year (all learning arrangements realised, interview 3). The focus groups at each school consisted of two to eight teachers who participated in the development and/or the realisation of one or more learning arrangements. As shown in Table 1 the composition of the focus groups varied somewhat across the study, as not all teachers were able to participate in each interview. For the second interview at the Alma Mater School only one teacher was available and the teachers at the Beech Grove School did not participate in the third round of interviews because the school left the project in the course of the second year (see also 3.2.5).

The interview protocol included topics concerning their participation in the project (e.g. ‘what are your experiences with the project so far?’), the technology that was used, and the role it played in the school’s classroom practice, (e.g. ‘to what extent are teaching and learning supported by technology in your school?’). The question what differences can be found between the school types with regard to the quantitative and qualitative technology integration (sub question 3) was answered based on the findings of the first two sub questions, as discussed in 2.4.

**Analysis**

The focus group interviews were transcribed. These transcriptions and the descriptions of the learning arrangements were subjected to both quantitative and qualitative content analysis (Huberman & Miles, 1994; Yin, 2011). In order to find indications of how the achieved integration of technology could be characterised we first selected fragments within the transcripts and the descriptions that contained relevant information on the newly developed technology use. We selected the fragments based on the occurrence of one or more of the following topics:

1. The school’s use of technology related to the developed learning arrangements.
2. The teachers’ account of the role that the developed use of technology played in their classroom practice.
Within the selected fragments we then coded for the following two themes:

A. Descriptions and teachers’ remarks with regard to the tools that were used.

B. Teachers’ remarks on the perceived value of the newly introduced technology, in terms of the technology being perceived as an integral part of their classroom practice.

Within the fragments coded as theme A we then distinguished between the following labels:

a. tools – what was used (how many different tools per learning arrangement)

b. tools – how many computers were available

c. tools – how many technology-enhanced learning arrangements were realised and how many were abandoned during the project

These labels were used for the quantitative characterisation of the technology integration. For theme B we used a grounded theory approach (Glaser & Strauss, 1967; Strauss & Corbin, 1998) to find types of teacher remarks that seemed to indicate that the technology was being perceived as an integral part of their classroom practice. With the labels for theme A (quantities of tools) and the characteristic teacher remarks for theme B (perceived value of technology) we then looked for patterns in the data with regard to these themes. After addressing sub questions 1 and 2 by discussing the patterns that emerged from this analysis, sub question 3 was answered by comparing the patterns across the school types to look for differences that might be attributed to the different educational concepts.

Results

The quantitative character of the technology integration at all five schools is presented first in this section. The qualitative results for the teachers’ perspective at the ‘traditional’ and the ‘innovative’ schools are discussed separately. Finally, we compare
the patterns of the teachers’ perspective between the school types. Tables 2 through 6 show what technology was used in each school, in the context of each learning arrangement. The activities or types of activities for which they were used are described in more detail in a previous study (de Koster, Kuiper, & Volman, 2012).

</tr>
</tbody>
</table>
At each school four learning arrangements were designed. The teachers at the ‘traditional’ schools developed relatively simple, transparent learning arrangements with one or two tools per arrangement and a varying intensity of technology use. At these schools all four learning arrangements were initially realised as planned. At the Princess Amalia School one learning arrangement was partly abandoned before the end of the project (the testing software in A1-1) and one was altered (the interactive use of the IWB in A1-2). The teachers' reflections on this are discussed in 3.2. The teachers at the three ‘innovative’ schools developed quite complex technology-supported learning arrangements, using a great variety of technology tools. The complexity of the learning arrangements presented the teachers at these schools with considerable logistical and technical challenges. At the Queen Beatrix School and the Beech Grove school this was one of the reasons why not all learning arrangements were realised. At the Beehive School all four learning arrangements were realised as planned, yet one was abandoned before the end of the project (B1-3).

*Quantities of tools*

No significant differences were found between the ‘traditional’ and the ‘innovative’ schools in terms of the total number of different tools that were used. In all five schools a combination of desktop and/or laptop computers and IWBs was used in most learning
arrangements. By the end of the project the IWB had replaced the traditional chalkboard in the participating classes in all five schools. In addition to these tools the ‘traditional’ schools used exercise and/or testing software in two out of four learning arrangements. Both ‘traditional’ schools used a total of seven tools (hardware and software) across the learning arrangements. At the ‘innovative’ schools the use of computers and the IWB was combined with the use of audiovisual tools and digital microscopes. At two of these schools a total of eight different tools was used, while at one school six different tools were used. However, when we look at the number of tools that were used within one learning arrangement, we find that at the ‘traditional’ schools only one to three different tools were used per learning arrangement (as can be seen in Tables 2 and 3), while at the ‘innovative’ schools most learning arrangements were supported by three or more tools (Tables 4, 5 and 6). The numbers of computers per class (desktop and laptop) did differ between the schools, but not between the school types, as shown in Table 7.

*Average number of computers per class, both desktop and laptop, based on number of computers and number of classes sharing computers
In three schools (one ‘traditional’ and two ‘innovative’) there were four desktop computers per classroom and at one of the ‘innovative’ schools there were also six shared desktop computers. In one ‘traditional’ school there were two desktop computers per classroom, and in one ‘innovative’ school most classes had none, yet at these schools there were more laptops per class. The laptops were shared among a number of classes in four out of five schools. So apart from the number of different tools per learning arrangement no clear distinctions could be found between the school types in quantitative terms.

**Integration of technology at the ‘traditional’ schools – the teachers’ perspective**

**Princess Amalia School**

According to the teachers at the Princess Amalia School the laptop computers soon became integrated into classroom practice of the participating classes during the first project year. The exercise software for mathematics (A1-1) and the exercise and test software for reading comprehension (A1-3) were also soon used routinely in all upper grades.

Int. 2  T1: It has become a logical whole. It soon became something logical. […] It became a self-evident use.

In general the convenience of the increased possibilities of the textbook-supporting software was mentioned as an important aspect several times by the teachers.

Int. 3  T3: I’ve mainly been doing the comprehensive reading [software]. That was just positive. That’s just going well. And yeah, it didn’t give me a lot of extra work, it feels like.
T1: Yes, I’m really happy with comprehensive reading on the computer too. I think that’s a real enrichment. Especially those [assignment] cards.

The mathematics testing software however (A1-1) was perceived as poorly usable and was therefore abandoned. During the implementation of the fourth learning arrangement (A1-4), the use of the available computers was intensified because of the focus on student use of the internet and presentation software in this learning arrangement. This may explain why by the end of the project the number of available computers was perceived by the teachers as insufficient even though at the end of the first year they had perceived the number of computers to be sufficient.

T2: […] we still don’t have enough computers. […] They need a lot of computers to search for information, to type in Word, to make a Powerpoint slideshow.

T4: So, yeah, for science and social science you couldn’t really do without.

T2: You really can’t.

The teachers seemed to unanimously perceive a wide availability of computers as indispensable for their classroom practice. The fact that by the end of the project the IWB had completely replaced the blackboard in the school shows that this tool was integrated as well. Nevertheless few explicitly positive comments about the IWB were made by the teachers during the focus group interviews. By the end of the project the board was still used in language lessons (A1-2), but in a less interactive way.

T1: At the start when I did that learning arrangement with spelling I made my own lessons [for the IWB]. But when can you do that? […] You scan your lesson and you do something with the board. But not all that’s possible.

Int: And that’s a matter of time?

T1: Yes. We have very little time.
The first learning arrangement at this school (A2-1) contained only a limited amount of technology use, restricted to laptops (e.g. for searching information in an information database) and infrequent use of the digital camera. This was due to the limited use of technology that was prescribed by the learning materials for this learning arrangement (i.e. the assignment cards, see Table 3. Also in the third learning arrangement (A2-3) technology use was limited. Here the software exercises from the math program replaced only the complementary (program-independent) online exercises that the pupils did previously. The teacher did not make use of the available options for differentiation in the software, because of the limited time for getting acquainted with the software and limited technical support. The IWB on the other hand was used regularly, replacing the chalkboard completely. The teachers gave several examples of ways in which the IWB was used ad hoc during instruction lessons to support the introduction of new concepts.

Int. 1  T3: Almost every day there is something of which we all say: ‘how exactly does that work?’ and we want to know more about it and you can show it right away [using the internet and IWB].

Int. 2  T2: [The IWB] is simply being used in the school. Yes. Daily. It is just in replacement of the chalkboard. It’s not like: right, now we’re going to do something with the IWB. That’s not what it’s like.

Grades 1 and 2 (combined in one class) received an additional fifteen laptops. By the end of the first year of the project, the teacher of this class indicated a strong increase in the computer use by her pupils, mainly on four laptops that were constantly available for the pupils in her classroom, ready to use. She was very enthusiastic about the increased possibilities for the students on the laptops.
Back then five minutes just wasn’t enough. You’d have to find a laptop, that was working, or didn’t have an empty battery. [...] And now we have it all ready at hand. And therefore they’re working on the laptops a lot more. And therefore they can do a lot more with them. I can use every five minutes. If they have nothing else to do, they can just sit down and do math or language or figure out something to do.

At this school as well, the teachers were very positive about the conveniences of the software that was linked to the learning materials that were used. The software to a large extent replaces the paper materials that were used before.

Now I’ve got it all digitally. [...] Before, I’d look up in the [teacher’s] manual what I’d have to do. But now it has everything, per day [it says] what we have to do that day. Also the worksheets, you know, the examples. Yes, everything is in it.

Integration of technology at the ‘innovative’ schools – teachers’ perspective

Beehive School

The first two learning arrangements at the Beehive School included the use of the IWB, both by the teachers and the pupils. The teachers initially also gave examples of using the IWB for activities outside the learning arrangements.

I wouldn’t want to miss [the IWB] anymore.

T2: It’s ideal. For example after the school holidays: ‘Where have you been on vacation?’. And then you google and search and you can fly across those mountains and ‘wow, here’s a lake’ and yes, that’s really cool. And educating.
Remarkably however, by the end of the second project year, the interviewed teachers at the Beehive School indicated that their appreciation and use of the IWB gradually decreased, although they did not abandon its use altogether. The laptop computers turned out to be more important to their teaching and learning than the IWB.

Int. 3  T4: We don’t have an IWB. But we will get one. Although we didn’t really miss it that much this year. Because if we wanted to do something we’d ask if we could use your board or something.
T1: For me that’s not the first thing that I would miss if it wasn’t there either. I think it’s very useful, I do see its added value, but actually I find the laptops far more important than the IWB.

In general the technology was perceived as obvious and indispensable. The tools had become ‘one of the materials’.

Int. 2  T2: I wouldn’t say it has become second nature to us, but it has become a normal learning material, just like the books you use, or whatever. Material. It’s just one of the materials. [Before] I would really have to think ‘how can I use film or visual material, or sound on MP3 players?’. I would really have to think hard to come up with something. From nothing, like. Yeah, and now I feel that I have a foundation on which I can build.

Int. 3  T1: I couldn’t do without anymore. […]
T4: I agree.
T1: But I also think it’s important for [the pupils] to use other sources as well.

With this and other remarks the teachers stressed that they find the use of technology in the classroom very important, while at the same time indicating that this importance is relative and analogue materials should be used as well, i.e. technology should be complementary to the traditional materials.
After designing the learning arrangements the teachers at the Queen Beatrix School initially expressed some fears of not being able to embed the new technology use in their everyday practice.

Int. 1  T1: […] When we started this project we had [the idea] that we could use the new tools in our classrooms and now it has come down to two separate workshops [outside of the classrooms]. Those are really cool and our ideas are in them but we haven’t discussed what we can do with [the tools] in our classrooms.

T3: A workshop is great but it’s something extra.

T1: It’s not your foundation.

After the first project year however, they made many remarks indicating their perception of the new tools as obvious and indispensable, both in the workshops and in the classroom.

Int. 2  T4: And now I can hardly imagine what we’d do without the cameras. [...] [the computer] is on…

T2: Yeah, that thing is on 24/7 almost.

Int. 3  T1: Yes, really a lot. A lot of things that you’re not really aware of. [...] It’s automatic, and then afterwards you [T9] say: but you also did this and that…

By the end of the third and final learning arrangement the time investment in the project did not feel like something extra anymore. It had fully replaced the way these projects had been carried out before the start of the project, when much less technology was used.
T9: [At the beginning of the project] there was simply not enough time. The children would come up to you and say: how does this [tool] work, how does that work? And if you as a teacher didn’t know then we just wouldn’t do it. […]
T1: Yeah, and also because it was something extra, like. Last year. Then that takes an effort in itself. And then in addition you’d have to figure out stuff, that turns out to be quite complicated. And this year it’s just a lot better, because it’s not something extra but it’s deepening something that you were already doing.

The IWB was used daily for presentations by pupils and for drawing mind maps, in addition to the planned and/or ad hoc illustration of topics during whole-class instruction by using the internet.

T6: [...] this afternoon we were doing experiments about fireworks and how it is made. Normally you’d search and fiddle for a long time and now you have a student look up the [recent] fireworks disaster on the computer. Before, ... well, you could order a video tape and it would take six weeks and it wouldn’t be meaningful for the kids. Now it’s very easy to ad hoc react to stuff that’s important for students. I find that a great advantage of this board.

T9: the other day we read a story about forest fires in comprehensive reading. Then you can immediately switch to the news, because there were forest fires in Australia. Then you can show yesterday’s news bulletin.

Beech Grove School

The technology use that was developed at the Beech Grove School was highly appreciated by the teachers. Several comments were made on the value of the IWB and the computers.
Int. 1 T1: At one point, just from the top of my head, I gave a lesson about the antiquity. [...] Just looked [it] up and talked about it. [...] I asked: what do you know about this? And a lot of stories came out. That’s just so meaningful. You just don’t get that in an ordinary history lesson.

Int. 2 T5: We had only two [computers] or so. [...] So you’d have to make the decision for yourself all the time: which child needs it the most at this moment? And that’s really hard. Because one uses it for spelling, the other for his research questions. And they all need it badly. So this is great, that it’s possible.

T2: At some point [the counsellor supporting the teachers] mentioned how much she enjoyed constantly seeing children working on the computers. Instead of being allowed a certain amount of time. They’re always in use.

The teachers also gave many examples of activities that have been made possible or a lot easier and more accessible by the use of technology, like writing on the computer instead of on paper, indicating that the technological tools are to an extent replacing the traditional means rather than complementing them.

Int. 2 T5: If you just look at the children that have difficulties writing. And write much longer texts on the computer than if they had to do it by hand. Or that they can add an image, which makes it fun of course. While before… [...] There’s so much more in it than in [the textbooks].

**Similarities and differences between the school types – the teachers’ perspective**

In this section we summarise the similarities and differences that were found in the teachers’ perception of the developed use of technology. We found the following types of remarks that seemed to indicate that the technology was perceived as an integral part of the teachers’ practice: technology perceived as common, matter-of-factly; technology perceived as indispensable; technology perceived as either replacing or complementing
the traditional tools. The following comparison between the school types was based on these characteristics of the teachers’ remarks. The quotes that are used to illustrate these similarities and differences are taken from the quotes presented above.

**Technology perceived as common**

At all five schools teachers’ comments showed they perceived most of their new technology use as common or obvious. This is reflected in phrases like ‘You’re not aware of that anymore because it’s so easy’ (Princess Amalia School, T4), ‘[The IWB] is simply being used’ (Alma Mater School, T2), ‘It’s just one of the materials’ (Beehive School, T2), and ‘A lot of things that you’re not aware of, it’s automatic’ (Queen Beatrix School, T1).

**Technology perceived as indispensable**

Similarly, at all five schools the teachers expressed perceiving their new technology use as indispensable, as reflected in phrases like ‘You couldn’t really do without’ (Princess Amalia School, T4), ‘I couldn’t do without anymore’ (Beehive School, T1), ‘I can hardly imagine what we’d do without the cameras’ (Queen Beatrix School, T4), and ‘[the pupils] all need it badly’ (Beech Grove School, T5). At one ‘traditional’ school one tool (math software) was abandoned because it did not function as expected. At one ‘innovative’ school on the other hand, one learning arrangement was ‘suspended’ because the ELE for which it was designed was not realised yet, which may have indicated implicitly that the ELE was perceived as indispensable even before it existed.

**Technology perceived as replacing and/or complementary**

With regard to the technology being perceived by the teachers as replacing and/or complementing the materials that were used previously a slightly more varied picture was found. In all five schools by the end of the project the IWB had replaced the
traditional chalkboard. It was highly valued for its multimodal possibilities, and especially the added value of visualizing lesson content on the IWB was mentioned frequently by teachers from both school types. The software used by the ‘traditional’ schools did both complement and replace the traditional materials, as computer exercises were combined with paper exercises and some paper tests were replaced completely by digital tests. At one of the ‘innovative’ schools the teachers agreed that the value of the technological tools is relative, as ‘it’s important for [the pupils] to use other sources as well’ (Beehive School, T1). At the other ‘innovative’ schools the enthusiasm about the value of technology seemed less conditional. At the end of the project the teachers at one of these schools agreed that the new use of technology was ‘not something extra’ anymore (Queen Beatrix School, T1) and at the other school the added possibilities of the tools were stressed, comparing ‘before’ (i.e. working on paper and in textbooks) with ‘now’ (working on the computer).

Conclusion

In this study five schools with either a ‘traditional’ or an ‘innovative’ school concept were studied as they participated in a two-year project of concept-guided development of instructional use of technology. We explored how the achieved integration of technology in two ‘traditional’ and three ‘innovative’ elementary schools that developed their use of technology in a concept-guided way could be characterised in quantitative and qualitative terms. We studied the technology-rich learning arrangements that were developed in this project (embedded case studies) and how the teachers perceived their newly developed technology use (focus group interviews), and we compared the emerging patterns between the school types.

Quantitative character of technology integration compared

The quantitative character of the integrated technology was measured through summarizing the number of different tools that were used in the learning arrangements and how many computers were available per class. When looking at the number of
different tools that were used we found that the ‘traditional’ schools tended to use less tools per learning arrangement than the ‘innovative’ schools. The numbers of computers per class (desktop and laptop) did differ between the schools, but not between the school types. Three schools (one ‘traditional’ and two ‘innovative’ schools) had an average of around seven computers per class, while at one ‘traditional’ and one ‘innovative’ school each class had around ten computers at its disposal. In one ‘traditional’ school one learning arrangement was partly abandoned before the end of the project and one was continued in a ‘toned-down’ fashion. At one ‘innovative’ school one learning arrangement was abandoned (suspended) before the end of the project.

Qualitative characterisation compared

The qualitative character of the integrated technology was measured through the value of the technology as perceived by the teachers. With respect to the labels ‘technology perceived as common’ and ‘technology perceived as indispensable’ no differences were found between the school types. At all five schools the technology that was used in the learning arrangements that were continued was in general perceived as common or ‘automatic’ and most of it also as indispensable. Both with regard to specific tools, like the IWB, and to technology in general teachers from both school types expressed that they ‘could not do without’ anymore, indicating that at least some of the tools and their applications were highly valued by these teachers. In all five schools some of the newly introduced technology replaced the non-digital materials while other tools merely complemented the existing materials or tools. All schools replaced the chalkboard with IWBs in all participating classes. The software used by the ‘traditional’ schools did both complement and replace the traditional materials. At the ‘innovative’ schools a slight within-group difference was seen between the schools. At one school the value of the new tools was explicitly put into perspective, the IWB being considered less important than the laptops and more stress being put on the complementary value of technology, while at the other two schools the tools seemed to be valued more unconditionally and more stress was put on technology replacing ‘the old’.
Discussion

Our findings suggest that a concept-guided development of technology use does promote the integration of the technology use that supports different pedagogies when defining technology integration in a qualitative way. This supports earlier findings that minimizing the distance between technology innovation and the school’s educational practice promotes technology integration (Zhao, Pugh, Sheldon, & Byers, 2002). We also conclude that the integration of technology at schools with different school concepts does not necessarily differ, which stands in contrast to the suggestion that the highest stage of technology integration is only found in a context of innovative, constructivist teaching and learning (Sandholtz, Ringstaff, & Dwyer, 1997; Mueller et al., 2008). To what extent exactly the achieved level of integration can be attributed to the concept-guided approach cannot be concluded from this exploratory study. More research is needed to investigate how and under which conditions concept-guided development of technology use promotes technology integration. Other factors are likely to have contributed to the achieved level of integration as well, like the teachers’ views and beliefs about technology at the outset of the project, their general attitude toward innovation, possible tensions within the teams of teachers-as-designers, the role of the counselors and school leaders and the support and resources that were provided. Further research is needed to gain more insight into these factors.

The data also suggest that what exactly is valued in the tools and applications that are used quite surprisingly does not vary greatly among the schools. Especially with regard to the IWB the teachers’ responses seemed to indicate that the multimodality of this tool and its possibilities for visualizing subject matter is valued equally in both school types. On the other hand, the interactive possibilities of the tool in terms of giving pupils more control over what happens on the board were not mentioned at any of the schools in the focus group interviews, even though in both school types we did observe this type of interactivity taking place (de Koster, Volman, & Kuiper, 2013). Did the teachers not value this affordance of the IWB as much as is generally expected, or were they simply not aware of their appreciation, taking it for granted already? Similarly, the fact that at one of the ‘innovative’ schools by the end of the project the teachers realised they
valued the laptop computers more than the IWB might be seen on the one hand as a failed integration of the IWB or on the other hand as a gradual articulation of the teachers’ ideas about their needs with regard to technology. Taking the affordances of technology for granted and developing more articulated ideas about technology in the classroom might be seen as additional signs that technology is becoming integrated in the teachers’ thinking and practice and thus need to be added to our conceptual framework for technology integration. These findings underscore the importance of the teachers’ perception of their technology use as a major indicator of technology integration and as a factor to be reckoned with when supporting a school in developing its technology use. More systematic reflection with teachers on their technology use can further enhance and inform the assessment of the level of technology integration, both for research purposes and for those involved in the actual development of technology use.

Finally, in this study we focused on the extent to which the teachers involved in this project succeeded in integrating technology into their classroom practices. The quality and outcomes of the teaching and learning, both before and after the integration of technology, were beyond the scope of this study, but obviously deserve equal attention. Further studies will therefore also have to focus on the extent to which the integrated technology use actually helps to improve these practices.
