Abstract
We present a two-parameter family of exactly solvable quantum many-body systems in one spatial dimension containing the Lieb–Liniger model of interacting bosons as a particular case. The principal building block of this construction is the previously-introduced (Stouten et al 2018 arXiv:1712.09375) family of two-particle scattering matrices. We discuss an $SL(2)$ transformation connecting the models within this family and make a correspondence with generalized point interactions. The Bethe equations for the ground state are discussed with a special emphasis on ‘non-interacting modes’ connected by the modular subgroup of $SL(2)$. The bound state solutions are discussed and are conjectured to follow some correlated version of the string hypothesis. The excitation spectrum of the new models in this family is derived in analogy to the Lieb–Liniger model and we show that for certain choices of parameters a spectrum inversion occurs such that the Umklapp solutions become the new ground state.

Keywords: integrable systems, Bethe ansatz, Lieb–Liniger type models, duality, Yang–Baxter equation, excitation spectrum

(Some figures may appear in colour only in the online journal)
Introduction

Exactly solvable models play a profound role in our understanding of low-dimensional statistical mechanics and condensed matter physics. Of particular importance is the Lieb–Liniger (LL) model, representing bosons in one spatial dimension interacting through a δ-function potential of arbitrary strength \( c \),

\[
H_{\text{LL}} = -\sum_{j=1}^{N} \frac{\partial^2}{\partial x_j^2} + c \sum_{i \neq j}^{N} \delta(x_i - x_j).
\]  

(1)

Originally employed to extend the Bogoliubov theory predictions for the excitation spectrum \([1, 2]\), it has emerged in quantum optics for modeling effective Kerr nonlinear media in the quantum regime \([3–5]\), and photonic many-body correlated states \([6, 7]\). In two-dimensional statistical mechanics this model appeared in the description of an interface interacting with impurities \([8]\), establishing a link of this problem to the Kardar–Parisi–Zhang universality class \([9–11]\). This could then also be connected to the asymmetric simple exclusion process, as discussed in \([12]\). Experiments with ultracold atomic systems can nowadays confine the motion of the constituent particles to one spatial dimension (1D), if the two-particle scattering is determined by an interaction of the δ-function form, then LL model emerges \([13]\). This model then describes experimentally observed phenomena such as interaction-induced fermionization of bosons \([14–16]\), suppression of three-body recombination \([17, 18]\), absence of thermalization \([19]\), stability in the attractive regime \([20]\), and Bloch oscillations in the absence of a lattice \([21]\). For a more detailed review we refer the reader to \([22]\).

However, the LL model does not exhaust all integrable continuum models in 1D. Gaudin \([23]\), Yang \([24, 25]\), and Sutherland \([26]\) demonstrated that the solution to the LL model can be further extended to a problem of δ-interacting particles with no limitation on the symmetry of the wave function. In particular, the Yang–Gaudin model is a generalization to interacting fermions, and multicomponent mixtures of point-interacting models have also been found by Sutherland. In the remarkable paper \([24]\), Yang then generalized the LL model to particles in arbitrary representations of the symmetric group.

The key ingredient of integrability in 1D is the Yang–Baxter equation (YBE) for the two-particle scattering matrices \( \tilde{S}_{ij}(k_i, k_j) \) of two particles labeled by \( i \) and \( j \), given by

\[
\tilde{S}_{ik}(k_i, k_j)\tilde{S}_{kj}(k_j, k_k)\tilde{S}_{jk}(k_k, k_j)\tilde{S}_{ij}(k_i, k_j) = \tilde{S}_{ij}(k_j, k_k)\tilde{S}_{ik}(k_k, k_i)\tilde{S}_{kj}(k_i, k_k)\tilde{S}_{jk}(k_j, k_i),
\]  

(2)

in which \( k \) is the scattering rapidity of a particle. The scattering matrix found by Yang \([24]\) was expressed in terms of the permutation operator \( \Pi_{ij} \), which interchanges quantum spaces of two interacting particles, reading as

\[
\tilde{S}_{ij}(k_i, k_j) = \Pi_{ij} - iF(k_i, k_j).
\]  

(3)

Using Artin’s braid relation for the permutation operator, \( \Pi_{12}\Pi_{23}\Pi_{12} = \Pi_{23}\Pi_{12}\Pi_{23} \), combined with the fact that \( \Pi_{ab}^2 = \text{I} \), one can easily see that the function \( F_{ij} \) has to satisfy the functional equation

\[
F_{ij}F_{ik} + F_{ik}F_{jk} = F_{ij}F_{jk}.
\]  

(4)

Yang found a particular solution to this equation,
where $c_0$ is a free parameter. By specifying a particular representation of the symmetric group generated by $\Pi_{ij}$ one can generate a large class of known continuum models. The LL model with $c = c_0^2$ follows from the totally symmetric representation, while the model of interacting spin-1/2 particles can be obtained by taking $\Pi_{ij} = \frac{1}{2}(1 + \vec{\sigma}_i \cdot \vec{\sigma}_j)$ with $\vec{\sigma} = (\sigma_x, \sigma_y, \sigma_z)$ the vector composed of the three Pauli matrices.

The purpose of this paper is to generalize the solution of Lieb and Liniger. In [27] we found a new solution to equation (4) in the class of rational functions. This solution is parametrized by two free (possibly complex) interaction parameters and thus generates a new class of integrable many-body 1D systems with possibly as many physical applications as the LL model. The symmetry properties and some consequences of this solution are discussed here. Numerical solutions of the resulting Bethe ansatz equations are presented and several important limits are analyzed. We conclude that the model introduces many surprises which await further analysis.

**Generalization of the model of interacting bosons**

The solution of any many-body problem starts with the analysis of the two-body case. A two-parametric generalization of the two-body scattering matrix from equation (5) was presented in [27], reading as

$$F_{ij} = \frac{c_0^2 + c_0 c_1 (k_i + k_j) + c_1^2 k_i k_j}{k_i - k_j}, \quad (6)$$

where both $c_0$ and $c_1$ are free parameters.

This two-parameter solution has two clear limiting regimes. Yang’s scattering matrix is reproduced in the $c_1 = 0$ case, leading to the bosonic LL model with the usual $\delta(x)$-interactions, whereas the $c_0 = 0$ case returns the scattering matrix used by Cheon–Shigehara (CS) [28, 29], representing a fermionic model with $\delta''(x)$ contact interactions. Furthermore, in the limit when only the first two terms in the numerator of $F_{ij}$ are kept, namely when $c_0 \gg c_1$, one should retrieve results similar to those found in [30–32], where the connection with anyonic models is studied.

**SL(2) group structure of the model**

In this section we repeat some of our previous findings [27] and specialize them to continuum models. Previously, we noted that our solution has an intrinsic SL(2) duality symmetry associated with a transformation of the rapidities combined with a transformation of the couplings $c_{0,1}$. One can notice that if we transform the rapidities $k_i$ and $k_j$ of the scattering matrix (3) and $F_{ij}$ from equation (6) according to the fractional-linear (Möbius) transformation,

$$\tilde{k}_{ij} = \frac{\alpha k_i + \beta}{\gamma k_i + \delta}, \quad \alpha \delta - \gamma \beta = 1, \quad (7)$$

the solution (6) remains the same iff we simultaneously transform the couplings $c_0$ and $c_1$ as

$$\begin{pmatrix} \tilde{c}_0 \\ \tilde{c}_1 \end{pmatrix} = \begin{pmatrix} \delta & \beta \\ \gamma & \alpha \end{pmatrix} \begin{pmatrix} c_0 \\ c_1 \end{pmatrix}. \quad (8)$$
Here, the unimodularity condition $\alpha \delta - \gamma \beta = 1$ is essential. The rapidities $k_i$ are in principle allowed to take arbitrary complex values (corresponding to bound states), so in principle the parameters $\alpha, \beta, \gamma, \delta$ could be complex as well, thus transforming under the group $SL(2, \mathbb{C})$ (the subscript $k$ denotes that they act on rapidities). At the moment, the couplings $c_{0,1}$ can be considered as complex as well. The $SL(2, \mathbb{R})$ transformation connects rapidities of different models with different coupling constants, and so it acts as a duality symmetry, similar to the electric-magnetic duality in field theory. In particular, the LL and CS models are connected by the inversion

$$k_j \leftrightarrow -k_j^{-1},$$

which would correspond to the $S$-transformation in the modular group case (see below).

Interestingly, one can understand the structure of the model by looking into the algebraic properties of $SL(2)$. Indeed, one can notice that the vector $(c_0, 0)^T$ (corresponding to the LL model) only undergoes a scaling when transformed by the upper-triangular matrices. The vector $(0, c_1)^T$ (corresponding to the fermionic model of CS) has the same property with respect to the lower-triangular matrices. Algebraically speaking, upper-triangular matrices represent interpretations as Euclidean rotations, while the hyperbolic elements correspond to squeeze mappings (the LL model), while the elliptic elements are responsible for the shear mappings (the LL model), while the elliptic elements are interpreted as Euclidean rotations, while the hyperbolic elements correspond to squeeze mappings (boosts) of the plane.

A particularly interesting subgroup of $SL(2)$ is given by $SL(2, \mathbb{Z})$, the group of matrices with integer elements and unit determinant. Indeed, we will show in the next section that this (modular) subgroup plays an important role in physics of the model.

The group-theoretical aspect of the model brings the following parallel with a problem of self-adjoint extension [33–36]. Consider a single particle problem, where the kinetic energy operator is defined as $K = d^2/dx^2$. The requirement of self-adjointness $\langle \psi K \psi \rangle = \langle \psi | K \psi \rangle$ in the domain $\Omega = R - \{0\}$ as written in coordinate representation translates into

$$0 = \int_\Omega dx [\psi^* K \psi - (K \psi)^* \psi]$$

$$= [\psi^* \psi' - (\psi')^* \psi] (0^+) - [\psi^* \psi' - (\psi')^* \psi] (0^-),$$

where we have applied integration by parts. This condition is equivalent to the requirement of probability current $j$ conservation across the boundary at $x = 0$, where $j = -i[(\psi')^* \psi - \psi^* \psi']/2$. Considering gluing conditions consistent with self-adjoint extensions at $x = 0$ for a function $\psi$ and its derivative $\psi'$, it was shown in [33] (see also section 1 of [36] for a review) that the most general gluing condition is given by

$$\begin{pmatrix} \psi(0^+) \\ \psi'(0^+) \end{pmatrix} = e^{i \phi} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \psi(0^-) \\ \psi'(0^-) \end{pmatrix},$$

where $\phi \in [0, \pi]$ and the real coefficients $a, b, c, d$ satisfy the unimodularity condition

$$ad - bc = 1.$$ (12)

The central point of this construction is the conservation of the probability current across the internal boundary. This can be compared with the case of the 1D Bose gas, where, because of
the bosonic symmetry of the wave function, regularity of the wave function has to be imposed, while its spatial derivative can experience a jump proportional to the interaction strength. In the case of fermions the opposite situation occurs—the derivative is continuous while the wave function exhibits a jump discontinuity. The most general potential \( v(x) \) respecting these internal jump boundary conditions is a combination of \( \delta(x), \delta'(x) \) and \( \delta''(x) \) [33–36],

\[
\frac{1}{2} v(x) = g_1 \delta(x) - (g_2 - ig_3) \frac{d}{dx} \delta(x) + (g_2 + ig_3) \frac{d}{dx} \delta(x) - g_4 \frac{d}{dx} \delta(x) \frac{d}{dx},
\]

(13)

where the parameters \( g_i, \ i = 1, \ldots, 4 \) can be related to the elements of the transfer matrix (11) across the boundary at \( x = 0 \). Note that the bosonic and fermionic limits nicely correspond to the lower- and upper-triangular matrices, similar to the discussion of \( SL_c(2) \) in the scattering matrix (note the transposition involved in going from \( SL_d(2) \) to \( SL_r(2) \)).

Combining this with explicit computations similar to [30], motivates us to conjecture\(^7\) that the scattering matrix corresponding to \( F_{ij} \) in equation (6) gives rise to the following many-body integrable Hamiltonian

\[
H_F = - \sum_{j=1}^{N} \frac{\partial^2}{\partial x_j^2} + \sum_{j<k}^{N} \left( c_0 - ic_1 \frac{\partial}{\partial x_j} \right) \left( c_0 - ic_1 \frac{\partial}{\partial x_k} \right) \times \delta(x_j - x_k),
\]

(14)

encompassing and extending both the LL and SC models.

It is known that the LL model corresponds to the nonlinear Schrödinger equation in the field theoretic formulation [36]. Inspired by this we propose that our Hamiltonian can be interpreted as a model which (a) incorporates a density–density interaction \( c_0^2 \rho(x) \rho(x) \), a density–current interaction \( c_0 c_1 \rho(x) j(x) \) and a current–current interaction \( c_1^2 j(x) j(x) \), where \( \rho = \Psi^\dagger(x) \Psi(x) \) and \( j(x) = \Psi^\dagger(x) \partial_x \Psi(x) \). In these terms, our duality collects the densities and currents into a unified object which transforms under the \( SL(2) \) group described above.

**Bethe ansatz equations and roots**

**Bethe equations and non-interacting modes**

While the \( SL(2) \) symmetry is preserved on the level of the scattering matrix and the YBE, it acts nontrivially on a system with fixed external boundary conditions, in that sense relating different physical models. Let us demonstrate this explicitly by constructing Bethe equations for our new solution (6) following the standard procedure. Namely, we impose periodic boundary conditions and move the particle \( j \) around a ring of size \( L \). Every time this particle experiences a collision with another particle (say \( i \)) a scattering phase shift \( S_{ij}(k_i, k_j) \) is collected. Moving the particle completely around the ring of \( N \) particles, the periodic boundary conditions impose a single-valued condition on the wave function which results in the consistency equations

\(^7\) Some preliminary steps where taken to show that the Hamiltonian (14) indeed results in the desired Bethe equations (15) with (3) and (6) in a similar spirit as [30]. This process for the potential (13) however has proven to be more subtle as in [30]. Because of the highly singular nature of the potential one has to deal with generalized functions (distributions) with great care, and therefore define a corresponding Hilbert space and matrix elements which could depend on the regularization procedure. In order not to overload the current paper this analysis will be continued in future work, in this sense the Hamiltonian is conjecture.
\[ e^{ik_jL} \prod_{i \neq j} S^F(k_j, k_i) = 1, \]  

where \( S^F(k_j, k_i) \) is defined as in equation (3) with \( F \) given by equation (6). It is important to note that here we assume that there is a basis in which the permutation operator which enters equation (3) can be chosen to be proportional to identity operator: \( \Pi_{ij} = \mathbb{1}^8 \). In this case equation (15) serve as generalized Bethe ansatz equations (BAE) which define the allowed values of the momenta \( k_i \).

Remarkably, it follows directly from equations (3) and (6) that there are special points in the space of rapidities when the scattering matrix trivializes, \( S^F(k_j, k_i) \equiv \mathbb{1} \). This happens when either one of the rapidities satisfies

\[ k_j = -\frac{c_0}{c_1}. \]  

In this case equation (15) implies \( \exp(ik_jL) = 1 \), which means that at these points there are free, non-interacting modes in a system with \( k_j = -c_0/c_1 = 2\pi n_j/L \) for integer \( n_j \in \mathbb{N} \). This quantization of couplings (in units of \( L \)) combined with the \( SL(2, \mathbb{R}) \) duality implies that a subgroup of the latter, the modular group \( SL(2, \mathbb{Z}) \) connects, in a sense of duality transformations, all free, noninteracting modes of the model. In the Yang model, the scattering function \( F_{ij} \) could vanish only if one of the momenta \( k_i \) or \( k_j \) becomes infinite. However, due to the symmetry in the new solution, this can happen at finite momenta as long as \( c_1 \neq 0 \). (Mapping Yang’s solution for \( k_{ij} \to \infty \) and \( c_1 = 0 \) to finite \( \hat{k}_{ij} \) always results in \( \hat{c}_1 \neq 0 \).) This vanishing has major consequences in both the Lieb–Liniger and the related Richardson–Gaudin class of models as introduced in [27]. Given an eigenstate in the Lieb–Liniger model, any particle with trivial scattering \( k = -c_0/c_1 \) can be added and the resulting state will still satisfy the Bethe ansatz equations provided the quantization condition \( k = \pm 2\pi n/L, n \in \mathbb{N} \) is simultaneously satisfied. While this restricts the values of \( c_0/c_1 \) for which such particles can be added for finite systems, this will always be possible in the thermodynamic limit. Here, the Bethe ansatz equations can be recast as a single integral equation, which will exhibit a singularity following from this non-interacting mode (see appendix).

**Ground state root distribution**

In the following sections the numerical solutions to the BAE (15) will be discussed. These solutions were obtained from the familiar logarithmic form of the BAE for real, fixed \( c_0 \) and varying \( c_1 \). In figure 1 the ground state solution of the BAE for different \( c_1 \) is given using as initial values \( c_1 \ll c_0 \) and \( c_1 \gg c_0 \), where the ground state is known, following from the correspondence to the LL and CS models. By ground state solution we mean the state following from the solution with (half) integer quantum numbers distributed around zero in these limiting cases. While the ground states are explicitly known in both limits, it can immediately be observed that the resulting solutions do not match. This implies a crossing between both ground states at some value of \( c_1 \neq 0 \), where the original solution will correspond to an excited state. This can be interpreted as a direct consequence of the non-interacting mode

---

8 The statement that \( \Pi_{ij} = 1 \) is a different way of saying that one is dealing with indistinguishable particles. In contrast, if one would consider ‘colored’ particles a more general representation of the permutation group is needed which would lead to a so-called nested Bethe ansatz. Therefore to be on the safe side we assume that our particles are indistinguishable, so that \( \Pi_{ij} = 1 \) and proceed with that. Our assumption is supported by the two limiting cases, \( c_1 = 0 \) (a Lieb–Liniger model of interacting bosons) and \( c_0 = 0 \) (a Cheon–Shigehara model) which do respect this property.
\( k = -c_0/c_1 \), since it is impossible for rapidities to cross this line as \( c_1 \) is changed. Indeed, if at some point \( k = -c_0/c_1 \), the resulting rapidity decouples from the system and remains a non-interacting mode as \( c_1 \) is varied (this can be easily seen in the thermodynamic limit). In the \( c_1 \ll c_0 \) limit the LL model is obtained, for which all rapidities at small values of \( c_1 \) lie at one side of the diverging line \(-c_0/c_1\). This can be contrasted with the CS limit, where the rapidities are symmetrically distributed around 0 for \( c_1 \to \infty \), and hence half the rapidities remain above and half below the non-interacting line \( k = -c_0/c_1 \) as \( c_1 \) is varied. As such, it is impossible to continuously deform these solutions into each other, and a level crossing (or multiple level crossings) needs to occur when changing \( c_1 \) between the two known limits.

As further illustration, the root density

\[
\rho \left( \frac{k_j + k_{j+1}}{2} \right) = \frac{1}{L(k_{j+1} - k_j)},
\]

is displayed in figure 2, where the solution starting from the LL limit exhibits the characteristic semicircular root density distribution around zero for \( c_1 = 0 \) [1]. Small positive and negative values of \( c_1 \) are also shown for comparison to the anyonic behavior at \( c_1 \ll c_0 \) [30, 31].

Due to decoupling of the roots at \( k_j = -c_0/c_1 \) the distributions of \( k_j \) convergence asymptotically to \(-c_0/c_1\). This is confirmed by the study of the weakly-interacting Gaudin limit \( c_0 \ll 1 \) (see below). Starting from \( c_1 \ll c_0 \) (LL initial conditions, main plot figure 1), \( c_1 \to \infty \) also results in a condensate around \( k_j = 0 \), which is surprising because in this limit the model should exhibit fermionic behavior as noted by CS [28]. Nevertheless, for large \( c_1 \) all roots have decoupled because they approach \( k_j = -c_0/c_1 \), which does happen in fermionic models and is not contradictory to the findings of CS.

The second initial value \( c_1 \gg c_0 \) can be considered a second Tonks–Girardeau limit in \( c_1 \), giving the same results as the single parameter case \((c_0 \gg 1 \text{ and } c_1 = 0)\), leading to

\[
\text{Figure 1. Ground state rapidity distribution for different values of } 0 \leq c_1 \leq 50 \text{ for } c_0 = 1, \text{ number of particles } N = 50 \text{ and system size } L = 100. \text{ The main plot corresponds to the rapidities obtained starting from the limit } c_1 \ll c_0 \text{ while the evolution of rapidities starting from the opposite limit } c_1 \gg c_0 \text{ is plotted in the inset. The line } k = -c_0/c_1 \text{ is plotted in dashed red.}
\]
\[ k_j = 2\pi n/L \quad \text{where} \quad n \in \mathbb{Z} \quad \text{(see figure 1)}. \] However, when approaching \( c_1 \sim 0 \) this limit does not retrieve the same state as obtained from the first initial value. Instead the upper roots tend to infinity and the lower roots approach the line \( k = -c_0/c_1 \). At this point the roots decouple and numerical analysis becomes unstable, leaving this region an open problem. This unstable behavior is only present in states that contain roots that hit the line \( k_j = -c_0/c_1 \). For highly excited states which have \( k_j > -c_0/c_1, \forall j = 1 \ldots N \) and \( \forall c_1 \geq 0 \) the two initial states do connect, since then all rapidities lie at the same side of the non-interacting line.

The overall connection of the CS and LL initial states thus remains an open problem. We conjecture that the solution seems to be related to states other than the ground state through the ‘non-interacting modes’ due to the asymptotic decoupling and the excitation spectrum as discussed in a later section.

We note that there is no definite property of the scattering phase with respect to \( k_j \to -k_j \) transformation. This is also manifested in both figures 1 and 2 that for \( c_1 \neq 0 \) the parity symmetry of the model is broken. We conjecture the following picture: Physically, the ground state perhaps can be interpreted in terms of two counter-propagating liquids with different densities and velocities. The overall momentum of all the above discussed states for any \( c_1 \) however vanishes (as confirmed by numerics). Furthermore the domain for \( c_1 < 0 \) shows exactly the same behavior as the previously discussed cases for \( c_1 > 0 \) except for an inversion of the root spectrum in \( k \) due to the line \( -c_0/c_1 \) now coming from above.

**Gaudin limit**

In order to better understand the asymptotic behaviour as the rapidities approach the line \( -c_0/c_1 \) for large \( c_1 \), the limit \( c_0 \ll 1 \) can be investigated, where the rapidities can be connected to the roots of orthogonal polynomials. In the LL model, it is known that for \( c_0 \ll 1 \) the rapidities can be obtained as roots of Hermite polynomials [37], and this can be extended to the current model for arbitrary \( c_1 \).
As shown in the appendix, a series expansion for the rapidities can be obtained as

\[ kj = -\frac{c_0}{c_1} + \frac{c_0 L}{c_1^2} z_j + \mathcal{O}(c_0^2), \tag{18} \]

with \( z_j \) the \( j \)th root of the associated Laguerre polynomial \( L_\alpha^N(z) \) with \( 1 + \alpha = L/c_1^2 \) \[38\]. These roots can be obtained for arbitrary values of \( \alpha \) by solving the recursion relation satisfied by the associated Laguerre polynomials (A.31) and are illustrated in figure 3. These results are in good agreement with the direct solution of the Bethe equations, as verified with the algorithm that generated figure 1.

This limit is termed the Gaudin limit because of the similarity of the approximate BAE with the previously-presented Gaudin equations \[27\]. For \( \alpha \) positive, it immediately follows from the properties of the associated Laguerre polynomials that all \( z_j \) are strictly positive and the rapidities lie above the line \(-c_0/c_1\) for all finite values of \( c_1 \), as previously observed in figure 1. This expansion can also be related to the known expansion for the LL model in the limit of small \( c_1 \). In this case, \( \alpha \) becomes large, and the roots of the associated Laguerre polynomials \( L_\alpha^N \) can be related to the roots \( y_j \) of the Hermite polynomials \( H_N \) as

\[ z_\alpha^0 \approx \alpha + \sqrt{2\alpha} y_j, \quad \text{for} \quad |\alpha| \to \infty. \tag{19} \]

Plugging this into the series expansion for \( k_j \) we obtain that for small \( c_1 \)

\[ k_j \approx -c_0 \sqrt{2} y_j + \mathcal{O}(c_0^2), \tag{20} \]

returning the known behaviour of the rapidities in the weakly-interacting Lieb–Liniger gas. For very large \( c_1 \), the eigenvalues become independent of \( c_1 \) and result in the zeros of \( L_{\alpha-1}^N \). This polynomial has a single root which goes to zero as \((1 + \alpha)/N\) for \( \alpha \to -1 \), and all other roots are non-zero for \( \alpha = -1 \). The exact values of these do not matter, since we see that in the limit of large \( c_1 \), the dominant term is given by
with a single rapidity behaving as
\[ k_j \approx \frac{c_0}{c_1} (N - 1) + \mathcal{O}(c_0^2). \]  
(22)

The existence of these two limits shows that in both cases, the series expansion was justified.

Non-analytic behaviour for \( c_0^2 \to 0 \) is obtained, similar to the LL model, since the interaction strength is determined by \( c_0^2 \) and the rapidities scale as the square root of the interaction strength. From the recursion relations satisfied by the associated Laguerre polynomials, the total momentum and energy follow as

\[ p(\{k_j\}) = \sum_{j=1}^{N} k_j = 0 + \mathcal{O}(c_0^2), \]

(23)

\[ E(\{k_j\}) = \sum_{j=1}^{N} k_j^2 = c_0^2 \frac{N(N - 1)}{L + c_1^2} + \mathcal{O}(c_0^2). \]

(24)

**Bound states**

The standard derivation of the structure of the spectrum for bound states spectrum (solutions corresponding to the complex values of rapidities) for both spin chains and continuum systems relies on the existence of a string hypothesis. This hypothesis states that in the \( L \to \infty \) limit the Bethe roots are arranged into sets of self conjugate complex numbers with equal real part known as the string centre. This configuration is not conserved for finite \( L \) where these strings are free to deviate from this configuration by some complex number \( \delta \). For more information see [39–41] and the references therein. The limiting case \( L \to \infty \) imposes certain constraints on the roots of the Bethe equations which are also present at large finite \( L \). Here we consider the simplest case of \( N = 2 \) for our model and show that the string hypothesis does not hold in its original form. We conjecture a structure of bound states spectrum for general \( N \).

Our derivation closely follows the one for the LL model. Namely, we start with the two-parametric Bethe equations (15)

\[ e^{ik_j L} = \prod_{i \neq j} \frac{k_j - k_i + i(c_0^2 + c_0c_1(k_j + k_i) + c_1^2k_jk_i)}{k_j - k_i - i(c_0^2 + c_0c_1(k_j + k_i) + c_1^2k_jk_i)}, \]

(25)

specified to \( N = 2 \),

\[ e^{ik_1 L} = \frac{k_1 - k_2 + i(c_0^2 + c_0c_1(k_1 + k_2) + c_1^2k_1k_2)}{k_1 - k_2 - i(c_0^2 + c_0c_1(k_1 + k_2) + c_1^2k_1k_2)}, \]

\[ e^{ik_2 L} = \frac{k_2 - k_1 + i(c_0^2 + c_0c_1(k_1 + k_2) + c_1^2k_1k_2)}{k_2 - k_1 - i(c_0^2 + c_0c_1(k_1 + k_2) + c_1^2k_1k_2)}. \]

(26)

Introducing real and imaginary parts of \( k \),

\[ k_j = u_j + iv_j, \quad j = 1, 2 \]

(27)

we compare the squared modulus of both sides of the first equation in (26)
\[
e^{-2vL} = \frac{A_+^2 + B_+^2}{A_-^2 + B_-^2}
\]

where
\[
A_\pm = u_1 - u_2 \pm c_1 [c_0 (v_1 + v_2) + c_1 (u_1 v_2 + v_1 u_2)]
\]
\[
B_\pm = v_1 - v_2 \pm [(c_0 + c_1 u_1) (c_0 + c_1 u_2) - c_1^2 v_1 v_2].
\]

In the limit of \( L \to \infty \) the left hand side vanishes (we postulate that \( v_1 > 0 \)), which implies that the two conditions should be satisfied simultaneously
\[
A_- = 0 \quad \text{and} \quad B_+ = 0.
\]

Multiplying the two equations in (26) implies that \( \exp [i(k_1 + k_2)L] = 1 \) which translates into
\[
v_1 + v_2 = 0.
\]

(31)

Substituting this into (29) gives
\[
(u_1 - u_2)(1 + c_1^2 v) = 0,
\]
\[
(c_0 + c_1 u_1) (c_0 + c_1 u_2) + c_1^2 v^2 + 2v = 0
\]

(33)

where \( v \equiv v_1 > 0 \) and so \( v_2 = -v \). The above conditions must be satisfied simultaneously.

Now, equation (32) implies that either
\[
u_1 = u_2 \quad \text{or} \quad v = -\frac{1}{c_1^2}.
\]

(34)

In the first case of (34) equation (33) can be written as an equation for a circle
\[
X^2 + Y^2 = R^2
\]

(35)

where
\[
X = c_0 + c_1 u, \quad Y = \frac{1}{c_1} + c_1 v, \quad R = \frac{1}{c_1}.
\]

(36)

This implies that the real and imaginary parts of the ‘string’ are correlated in a special manner.

For the second case in (34) equation (33) implies that \( u_1, u_2 \) and \( v \) are mutually correlated,
\[
U_1 U_2 = \frac{1}{c_1^2}, \quad \text{where} \quad U_{1,2} = c_0 + c_1 u_{1,2}.
\]

(37)

We note that since according to our convention \( v > 0 \), it follows that \( c_1 \) is purely imaginary.

Interestingly, one can arrive to the same conclusion by first applying the \( SL(2) \) transformation of \( k_j \) to (25),
\[
k_{j,\ell} \rightarrow y_{j,\ell} = \frac{k_{j,\ell}}{1 + \frac{c_1}{c_2} k_{j,\ell}}
\]

(38)

which transforms the right hand side of (25) to the LL form, and then follow the same analysis as above. This is nothing but a manifestation of the geometrical property of the Möbius transformation: circles and lines (thought as circles of infinite radius) are transformed into circles and lines respectively.

By looking into the case of \( N \geq 3 \) one can convince oneself that the requirement for numerator or denominator to vanish (which is coming from the vanishing or divergence condition
respectively of the left-hand side of the Bethe equation) occurs only for a single factor in (25) for a given \( k_j \). This implies certain correlation between real and imaginary parts of the roots. While we cannot advance analytically anymore, we formulate a

Conjecture: Real and imaginary parts of the roots of Bethe equations are correlated and live on domains which have proper transformation properties with respect to the action of the \( SL(2) \) (like e.g. circles and lines).

This conjecture can further be supported by the Gaudin limit (see appendix), where the BAE roots occupy a spectral curve of the Heine–Stieltjes type differential equation. Moreover it was noticed in [42, 43] that the bound state solutions in the model with \( \delta \) and \( \delta' \) interactions (which can be regarded as a special limit of small \( c_1 \) of the present model, such that \( c_1^2 \) term is neglected while the \( c_0c_1 \) term is kept) are situated on circles with angular positions which follow a pattern of Farey sequences in the \( L = \infty \) limit. We note that the modular group \( SL(2, \mathbb{Z}) \) is an automorphism group of the Farey sequence. It would be very interesting to study these connections further.

Excitations

In order to discuss the excitation spectrum we distinguish between Type-I (particle) and Type-II (hole) excitations, following Lieb [2]. We restrict ourselves to the \( c_0 \gg c_1 \geq 0 \) initial condition, in this case the negative momenta states give rise to new behavior because they approach the decoupled regime around \( k_j = -c_0/c_1 \). All excitations with positive momenta give similar results to the ground state because the roots never reach the line \(-c_0/c_1\). For negative \( c_1 \) and \( c_0 \gg -c_1 \geq 0 \) the root spectrum inverts around \( k \) (as mentioned above) and similar behavior is observed for excitations with positive momenta whereas negative momentum excitations remain similar to the ground state.

In figure 4, the spectrum for \( N = 10 \) is given with unit filling \( N/L = 1 \), where again

\[
E(\{k_j\}) = \sum_{j=1}^{N} k_j^2, \quad p(\{k_j\}) = \sum_{j=1}^{N} k_j.
\]

(39)

Note that the choice of low \( N \) is for illustrative purposes only, since large \( N \) exhibits the same qualitative behavior. While the excitation spectrum remains similar for Type-I excitations for different values of \( c_1 \) (figure 4 top right). The Type-II excitations lose their characteristic quadratic behavior and tend to \( E \sim p \) instead of \( E \sim |p| \) as expected for fermions. Comparing the bottom panels of figure 4 the energies of the Type-II excitations for larger \( c_1 \) becomes strictly increasing with respect to the momenta, the linear behavior becomes more obvious for increasing \( c_1 \). This behavior is confirmed by the evaluation of the energy of negative momenta Type-II excitations as a function of \( c_1 \) in figure 5. A full inversion of the spectrum occurs at \( c_1 \sim 3.5 \), which means that the spectrum reorders and becomes strictly increasing as expected.

Unfortunately, we were unable to continue our analysis of the negative momenta states to increasingly negative momenta or higher \( c_1 \) because these have the same numerical instabilities as the \( c_1 \gg c_0 \) initial condition states near \( c_1 \to 0 \), where some of the rapidities hit the line \( k = -c_0/c_1 \).

Conclusion

Based on a previously-presented general solution of the rational Yang–Baxter equation [27], we initiated the studies of a generalized model of an interacting one-dimensional gas. Our
The first guess was that these particles can, presumably, be interpreted as anyons in the spirit of [30–32], since the different limits of this model return either interacting bosons with $\delta$ interaction or CS model with $\delta''$ interaction. However if our conjectured form of the Hamiltonian (14) is correct, our model may be seen as the one containing density-current (mixed $c_0c_1$ term) and current–current interactions ($c_1^2$ term), in addition to the density–density coupling
(traditional $c_0^2$ term). The $SL(2)$ acts then as a duality between density and current. This interpretation partially explains the title of this paper.

The interaction structures follow from study of the contact interactions [33–36] which can be related to different subgroups of $SL(2)$. The standard ($\delta$) interaction corresponds to the upper parabolic block of the transformation matrix (Borel subalgebra) while the lower parabolic group, related by the $S$-duality with the former, is given by the lower parabolic block and corresponds to the $\delta''$ interaction. The diagonal subalgebra corresponds to either the elliptic or hyperbolic block and is connected with $\delta$ interaction.

The Bethe ansatz equations are obtained assuming that there exists a basis where the permutation operator acts as an identity, and are solved both numerically and by connecting the rapidities to roots of orthogonal polynomials in the weakly interacting limit. Also the excitation spectrum is presented. A particular feature of the presented model is the presence of non-interacting modes at specific values of the interaction constants, which prevents the ground states of the corresponding fermionic and bosonic limiting models from being smoothly connected. These modes are connected by the modular $SL(2,\mathbb{Z})$ subgroup of $SL(2)$.

We further conjecture that the string hypothesis should perhaps be generalized to more general domains of the rapidities complex plane. We believe that future studies of the presented model will encounter new surprises and mathematical richness.

Appendix

Derivation of the integral equation

Here we outline a derivation of the integral equation in the continuum limit $L \to \infty$, $N \to \infty$, $N/L = \rho_0 = \text{const}$, though we believe that it has limited application because of singularities contained in the kernel. These singularities can be extracted to the driving term by use of the transformation (38) which cleans up the kernel but results in the same singular behavior.

We start with the equation (15) in its explicit form

$$e^{ik_jL} = \prod_{l \neq j}^{N} \frac{k_j - k_l + i(c_0 + c_1k_j)(c_0 + c_1k_l)}{k_j - k_l - i(c_0 + c_1k_j)(c_0 + c_1k_l)}$$

(A.1)

The usual strategy of analyzing these coupled transcendental equations is to consider a logarithm of its both sides

$$Lk_j + \sum_{l=1}^{N} \theta(k_j, k_l) = 2\pi \left( n_j - \frac{N+1}{2} \right)$$

(A.2)

where \( \{n_j\}, j = 1, \ldots, N \) is a set of integers, and
\[ \theta(k_j, k_l) = i \ln \left( \frac{f(k_j, k_l) + (k_j - k_l)}{f(k_j, k_l) - (k_j - k_l)} \right) \]  
(A.3)

is a scattering phase shift. Here
\[ f(k_j, k_l) = c^2_0 + c_1 c_0 (k_j + k_l) + c^2_1 k_j k_l. \]  
(A.4)

The kernel (A.3) is an antisymmetric function and therefore
\[ \sum_{j,l=1}^{N} \theta(k_j, k_l) = 0, \]  
(A.5)

which implies that
\[ L \sum_{j=1}^{N} k_j = 2\pi \sum_{j=1}^{N} \left( n_j - \frac{N+1}{2} \right) \]  
(A.6)

and we can interpret \( \sum_{j=1}^{N} k_j \) as a total momentum.

One can bring the phase shift to the Lieb–Liniger form by applying a particular SL(2) transformation
\[ k_{j,l} \rightarrow y_{j,l} = \frac{k_{j,l}}{1 + \frac{c_0}{c_1} k_{j,l}}. \]  
(A.7)

By considering the extended complex plane of \( k_{j,l} \) augmented by the point at infinity, we can formally allow singularities in the kernel \( \theta(k_j, k_l) \). In terms of the \( y_j \)-variables the Bethe Ansatz equation gets the following form
\[ L \left( \frac{y_j}{1 - \frac{c_0}{c_1} y_j} \right) + \sum_{k=1}^{N} \theta_{LL}(y_j - y_k) = 2\pi \left( j - \frac{N+1}{2} \right) \]  
(A.8)

where
\[ \theta_{LL}(k) = i \ln \left( \frac{i c^2_0 + k}{i c^2_0 - k} \right). \]  
(A.9)

Introducing the root density as
\[ \rho(y_j) = \frac{1}{L(y_{j+1} - y_j)}, \]  
(A.10)

\[ \sum_{j=1}^{N} = L \sum_{j=1}^{N} \rho(y_j) (y_{j+1} - y_j) \]  
(A.11)

\[ \sum_{j=1}^{N} f(y_j) \rightarrow L \int_{A}^{B} dy \rho(y) f(y) \]  
(A.12)

for arbitrary function \( f(y) \), we subtract equation (A.8) for \( y_{j+1} \) from the same equation for \( y_j \) and obtain
\[ L \frac{c_0}{c_1} \left( \frac{1}{1 - \frac{c_0}{c_1} y_{j+1}} - \frac{1}{1 - \frac{c_0}{c_1} y_j} \right) \]  
(A.13)
\[ + (y_{j+1} - y_j) \sum_{i=1}^{N} \theta'(y_j - y_i) = 2\pi \]  
(A.14)

as \( N, L \to \infty \). Here \( \theta'_{LL}(y - y_m)(y_{j+1} - y_j) = \theta_{LL}(y_{j+1} - y_m) - \theta_{LL}(y_j - y_m) \) and we also assume that the boundaries of integration \( A = -B = -\Lambda \). Finally, expanding around small \( \delta y = (y_{j+1} - y_j) = \frac{1}{\rho(y)} \) and assuming that terms of \( O(\delta y^2) \) can be neglected

\[
\left( \frac{1}{1 - \frac{a}{\rho} y_{j+1}} - \frac{1}{1 - \frac{a}{\rho} y_j} \right) \approx \frac{c_1}{c_0 L} \rho(y) \left( \frac{1}{1 - \frac{a}{\rho} y} \right)^2
\]  
(A.15)

we obtain

\[
\rho(y) = \frac{1}{2\pi} \int_{-\Lambda}^{\Lambda} dx' \rho(x) K(x, y) = \frac{1}{2\pi} \frac{1}{(1 - \frac{a}{\rho} y)^2}
\]  
(A.16)

where

\[
K(x, y) = \frac{2c_0^2}{c_0^4 + (x - y)^2}
\]  
(A.17)

and we have to supplement (A.16) by the normalization condition

\[
\int_{-\Lambda}^{\Lambda} \rho(y) dy = D = \frac{N}{L}.
\]  
(A.18)

The final step, which is very convenient for the numerical implementation is to perform the following change of variables,

\[
c_0 = \Lambda^2 \alpha, \quad c_0 c_1 \equiv \beta^2, \quad y = \Lambda k, \quad \rho(\Lambda y) = g(k)
\]  
(A.19)

in terms of which we have the following system

\[
g(k) = \frac{\alpha^2}{\pi} \int_{-1}^{1} \frac{g(p) dp}{\alpha^2 + (k - p)^2} = \frac{1}{2\pi} \frac{1}{(1 - \frac{\beta}{\alpha} k)^2}
\]  
(A.20)

\[
\gamma \int_{-1}^{1} dk g(k) = \alpha^2
\]  
(A.21)

where \( \gamma = c_0^2 / D \).

Alternatively, one can perform the same analysis without making use of the \( SL(2) \) transform while dealing directly with the modified kernel (with respect to the LL kernel)

\[
\tilde{K}(k, q) = \frac{(\alpha^2 + \beta^2 k)(\alpha^2 + \beta^2 q) - \beta^2(k - q)(\alpha^2 + \beta^2 q)}{(\alpha^2 + \beta^2 k^2)(\alpha^2 + \beta^2 q^2) + \alpha^2(k - q)^2}.
\]  
(A.22)

We end up with the following equation then

\[
g(k) = \frac{\alpha^2}{\pi} \int_{-1}^{1} dq g(q) \tilde{K}(k, q) = \frac{1}{2\pi}
\]  
(A.23)

supplemented by \( \gamma \int_{-1}^{1} dk g(k) = \alpha^2 \).

The assumption that we can perform a Taylor expansion for arriving to the integral equation is crucial here. This assumption is however only justified if the \( \frac{\alpha}{c_1} > |\Lambda| \) or \( \frac{\beta}{\alpha} < 1 \) which
in general is not true for all parameters $c_{0,1}$. At these same points the modified kernel becomes singular which is also reflected in a singular behavior of the finite density, figure 2. An attempt was made to solve these equations numerically, for the case where $\frac{c_0}{c_1} > |\Lambda|$ the numerics correspond to the finite density behavior, however we were unable to continue our studies outside this regime.

**Gaudin limit**

Starting from the Bethe ansatz equations (15)

$$e^{\delta_j L} = \prod_{l \neq j} \frac{k_j - k_l + i(c_0 + c_1 k_j)(c_0 + c_1 k_l)}{k_j - k_l - i(c_0 + c_1 k_j)(c_0 + c_1 k_l)}, \quad (A.24)$$

a series expansion for the rapidities can be obtained in orders of $c_0$ if $c_0 \ll 1$. We propose an expansion similar to the weakly-interacting limit of the Lieb–Liniger gas with

$$k_j = c_0 \delta_j + O(c_0^2), \quad (A.25)$$

in which $j = 1 \ldots N$ and $\delta_j$ is finite and independent of $c_0$. Up to zeroth order in $c_0$, the BAE becomes $1 = 1$, which is trivially satisfied. The first-order correction on the equation (A.24) is then given by

$$\delta_j L = 2 \sum_{l \neq j} \frac{(1 + c_1 \delta_j)(1 + c_1 \delta_l)}{\delta_j - \delta_l}. \quad (A.26)$$

In taking this series expansion, we have made the assumption that $c_1 \delta_j$ remains bounded for all values of $c_1$. This is expected for small $c_1$ and can be verified afterwards for large $c_1$. The equation (A.26) can again be linked to the roots of orthogonal polynomials. Performing the substitution $\delta_j = -\frac{1}{c_1} + \frac{1}{c_1 z_j}$ and multiplying the equation with $-c_1/L$ results in

$$1 - \frac{L/c_1^2}{z_j} = 2 \sum_{l \neq j} \frac{1}{z_j - z_l}. \quad (A.27)$$

The associated Laguerre polynomials $L_\alpha^N(z)$ satisfy the differential equation

$$z P''(z) + (1 + \alpha - z) P'(z) + N P(z) = 0, \quad (A.28)$$

where from the Heine–Stieltjes connection [38] the roots $z_j$ are coupled through

$$1 - \frac{1 + \alpha}{z_j} = 2 \sum_{l \neq j} \frac{1}{z_j - z_l}. \quad (A.29)$$

Taking $1 + \alpha = L/c_1^2$, this returns the proposed series expansion as

$$k_j = -\frac{c_0}{c_1} + \frac{c_0 L}{c_1^2 z_j} + O(c_0^2), \quad (A.30)$$

with $z_j$ the $j$th root of the associated Laguerre polynomial $L_\alpha^N(z)$ with $1 + \alpha = L/c_1^2$. This is known as a Laguerre function for non-integer values of $\alpha$, satisfying the following recursion relation

$$NL_\alpha^N(x) = (2N - 1 + \alpha - x)L_\alpha^{N-1}(x)$$

$$- (N + \alpha)L_\alpha^{N-2}(x), \quad (A.31)$$
from which the roots can be determined for arbitrary values of $\alpha$. These also satisfy

$$L_N^0(0) = \binom{N + \alpha}{N},$$  \hfill (A.32)

and derivatives can be found as

$$\frac{d^k}{dx^k} L_N^0(x) = (-1)^k L_N^{\alpha+k}(x),$$  \hfill (A.33)

for $k < N$. The roots of the polynomial $P(z) = L_N^0(z)$ can then be easily shown to satisfy

$$\sum_{j=1}^{N} \frac{1}{z_j} = -\frac{P'(0)}{P(0)} = \frac{N}{1 + \alpha},$$  \hfill (A.34)

$$\sum_{j=1}^{N} \frac{1}{z_j^2} = \left(\frac{P'(0)}{P(0)}\right)^2 - \frac{P''(0)}{P(0)} = \frac{N(N + 1 + \alpha)}{(1 + \alpha)^2(2 + \alpha)}.$$

Using this in the expansion for the rapidities then returns the results presented in the main text.

Interesting things happen if we plot the rapidities $k$ for both $c_0$ and $c_1$ purely imaginary, as done in figure A1. Now the rapidities start as purely imaginary for $c_1 = 0$ as expected for the attractive LL case [40, 41], but obtain a real part for non-zero $c_1$. Remarkably, the approximation breaks down at values of $c_1^2 = -L/m, m = 1 \ldots n$. At these points, the Laguerre
polynomials have zero as root, and the first-order contribution diverges. It should be checked numerically what happens at these points if we solve the full Bethe equations rather than the first-order approximation. This also allows for a crossing of the line \(-c_0/c_1\) if we consider the large \(c_1\) limit. Again, at both small and large \(c_1\) the approximation holds, but at intermediate \(c_1\) the approximation breaks down at exactly \(c_1^2 = -L/m, m = 1 \ldots n\), where the numerical error on the Bethe equations becomes large. However, if we plot the energy, these divergences cancel exactly except for \(c_1^2 = -L\), where the energy first dives towards minus infinity for \(|c_1|^2 < L\) and returns from plus infinity for \(|c_1|^2 > L\). This is consistent with the resulting expression for the total energy (24).
