Interstitial cells of Cajal are involved in the afferent limb of the rectoanal inhibitory reflex

F de Lorig, W J de Jonge, T Wedel, J M Vanderwinden, M A Benninga, G E Boeckxstaens

Background and aims: Interstitial cells of Cajal (ICC) have been shown to be involved in nitricergic neurotransmission of the lower oesophageal sphincter and pylorus. Here we studied the role of ICC and nitric oxide (NO) in the inhibitory neurotransmission of the murine internal anal sphincter (IAS).

Methods: The rectoanal inhibitory reflex, rectal compliance, and relaxation of the isolated IAS to electrical stimulation were measured in controls, KIT W/KIT Wv mice, and neuronal NO synthase (nNOS) deficient mice. In addition, we evaluated the effect of blockade of nNOS using N-nitro-L-arginine methyl ester (L-NAME). Distribution of nNOS positive neurones and ICC in the IAS was assessed immunohistochemically.

Results: KIT W positive ICC were present in a dense network in the IAS of controls but not in KIT W/KIT Wv mice. Relaxation of IAS muscle strips induced by electrical stimulation was diminished in nNOS W/KIT Wv mice. Blockade of NOS reduced the relaxation of IAS muscle strips in both mice. Relaxation of the IAS to rectal distension was significantly diminished in KIT W/KIT Wv mice and nNOS deficient mice. In concert, in vivo blockade of NOS attenuated the relaxation of the IAS in controls. No significant difference in compliance was found.

Conclusion: The inhibitory innervation of the IAS and the rectoanal inhibitory reflex are mediated by NO and the rectoanal inhibitory reflex requires an intact network of ICC in the IAS. Thus both loss of nitricergic innervation and deficiency of ICC lead to impaired anal relaxation and may play an important role in rectal evacuation disorders.

Materials and Methods

Animals

Adult KIT W/KIT Wv mice (20–30 g) and their wild-type (KIT W/+ ) controls, as well as neuronal nitric oxide synthase (nNOS) deficient mice (18–28 g) and their respective wild-type controls (site bred C57BL/6J) were purchased from the Jackson Laboratory (Bar Harbor, Maine, USA). For immunohistochemical studies, transgenic mice were used that carry the KIT W lacZ allele (“lacZ positive controls”),10–13 KIT W lacZ/KIT Wv lack ICC,14 similar to the more extensively studied KIT W/KIT Wv animals,15 and will be referred to as “ICC deficient animals”.

All animals were maintained under controlled conditions and were used at 8–12 weeks of age. Experiments were approved by the Ethical Animal Research Committee of the University of Amsterdam, the Netherlands, and by the Faculty Committee for Use of Laboratory Animals of the Faculté de Médecine, Université Libre de Bruxelles, Belgium.

Immunohistochemistry

Fresh frozen anorectal specimens of control and KIT W/KIT Wv mice were harvested for longitudinal cryosections, while paraformaldehyde fixed specimens of control (KIT W/KIT Wv) and KIT W lacZ/KIT Wv mice were harvested for transverse and longitudinal cryosections as well as for whole mount preparations, as described previously.10 13

Whole mounts: preparation and immunohistochemistry

After preincubation with 10% normal mouse serum, samples were incubated overnight with the KIT goat and the nNOS rabbit antisera (Santa Cruz Biotechnology, Santa Cruz, California, USA) diluted in Tris buffered saline-Triton X (TBS-TX) containing 1% normal horse serum (NHS). Samples were then rinsed in TBS, incubated in the dark for one hour at room temperature in TBS containing donkey anti-rabbit antiserum coupled to FITC (Jackson Immunoresearch Laboratories, West Grove, Pennsylvania, USA) and biotinylated donkey anti-goat antiserum (Jackson Immunoresearch Laboratories, West Grove, Pennsylvania, USA).

Abbreviations:

IAS, internal anal sphincter; ICC, interstitial cells of Cajal; nNOS, neuronal nitric oxide synthase; NO, nitric oxide; RAIR, rectoanal inhibitory reflex; IAS, internal anal sphincter; LOS, lower oesophageal sphincter; TBS-TX, Tris buffered saline-Triton X; NHS, normal horse serum; NAANC, non-adrenergic non-cholinergic; SNP, sodium nitroprusside; ATP, 5’-adenosine triphosphate
Sections: preparation and immunohistochemistry
Specimens were fixed overnight in fresh 4% paraformaldehyde solution in phosphate buffered saline, pH 7.4, at 4°C, cryopreserved in graded solutions of sucrose (10–30%), embedded in Tissue-Tek OCT compound (Miles, Elkhart, Indiana, USA), oriented either transversely or longitudinally, and snap frozen in 2-methyl butane at −80°C. Sections (15 mm thick) were cut on a cryostat and mounted on slides coated with 0.1% poly-L-lysine.

After preincubation with NHS, sections were exposed overnight at room temperature to KIT goat antiserum (Santa Cruz Biotechnology) diluted 1/500 in TBS-TX containing 1% NHS, rinsed in TBS, incubated for one hour at room temperature in TBS containing biotinylated donkey antigoat antiserum (Jackson) diluted 1/200, rinsed in TBS, and finally incubated in the dark for one hour at room temperature in a mixture of 95% O2 and 5% CO2. Sections were then transferred onto a glass slide coated with 0.1% poly-L-lysine and were cut into two equal parts. Coverslips were mounted with “Slow Fade Light” antifade mounting medium (Molecular Probes, Eugene, Oregon, USA) before viewing on a confocal microscope (MRC 1024; Bio-Rad Laboratories, Hemel Hempstead, Hertfordshire, UK) fitted on an inverted microscope equipped with a Plan-Neofluar 40×/1.3 oil immersion objective (Axiovert 100; Zeiss, Oberkochen, Germany). As KIT-ir appeared fairly weak in ICC deficient animals with the fluorescent detection system, the more sensitive detection system using peroxidase was additionally applied.

In vitro studies
Organ bath experiments
KIT+/−/KIT W−/Wv mice, nNOS−/−, and control mice were killed by cervical dislocation. The perianal skin was excised and the anus and terminal rectum were quickly removed and placed in a glass slide coated with 0.1% poly-L-lysine and were cut into two equal parts. Coverslips were mounted with “Slow Fade Light” antifade mounting medium (Molecular Probes, Eugene, Oregon, USA) before viewing on a confocal microscope (MRC 1024; Bio-Rad Laboratories, Hemel Hempstead, Hertfordshire, UK) fitted on an inverted microscope equipped with a Plan-Neofluar 40×/1.3 oil immersion objective (Axiovert 100; Zeiss, Oberkochen, Germany). As KIT-ir appeared fairly weak in ICC deficient animals with the fluorescent detection system, the more sensitive detection system using peroxidase was additionally applied.

In a second series, the effects of N-nitro-L-arginine methyl ester (L-NAME 200 μmol/l), the blocker of neuronal conduitance tetrodotoxin (2.0 μmol/l), the blocker of P2 purinergic receptors suramin (100 μmol/l), and the combination of L-NAME and suramin were investigated on the responses to electrical impulses, to ATP (1.0 mmol/l), and to SNP (2.5 mmol/l). L-NAME and suramin were added at least 20 minutes before the experiments.

In vivo studies
Anorectal manometry
Anorectal perfusion manometry was performed with a purpose built micromanometric anorectal catheter (outer diameter 0.8 mm). The polyimide catheter incorporated an array of four side holes spaced 0.5 mm apart for measurement of anal sphincter pressure and basal pressure within the rectum. All side holes were perfused with sterile degassed water at a rate of 0.02 ml/min. A polyethylene balloon was located proximally to the catheter to distend the rectum.

Protocol
Anorectal manometry was performed in anaesthetised mice. Mice were anaesthetised by intraperitoneal injection of a mixture of fentanyl citrate/fluanisone (Hynpnom; Janssen Pharmaceuticals, Beerse, Belgium) and midazolam (Dormicum; Roche, Mijdrecht, the Netherlands) at 0.07 ml/10 g (fentanyl 0.32 mg/ml, fluanisone 10 mg/ml, midazolam 5 mg/ml). The catheter was positioned with at least two side holes straddling the anal sphincter high pressure zone and one side hole in the rectum. After positioning, basal anal sphincter pressure was recorded. Thereafter a polyethylene rectal balloon was introduced and positioned aside the manometric catheter. After an equilibration time of 15 minutes, graded rectal distensions of 10 seconds were applied using the polyethylene balloon (0.25–0.40 ml air insufflation) to evoke IAS relaxations. Consecutive rectal distensions were performed at one minute intervals and distensions were repeated three times at each volume. This distension protocol was repeated after addition of L-NAME (100 mg/kg intraperitoneally).

In a separate series of experiments, rectal compliance was measured with a non-compliant (polyethylene) balloon with a maximum capacity of 0.45 ml. The balloon was fixed on a silicone catheter with a diameter of 1 mm. This catheter was connected to a pressure transducer measuring intraballoonal pressure during stepwise volume controlled distension (0.04–0.40 ml).

Data analysis
Basal IAS pressures were obtained from the baseline period preceding the distension protocol. A drop in anal sphincter pressure of at least 5 mm Hg over 2–5 seconds, was identified as a RAIR. If rectal distension resulted in a RAIR, the amplitude of each relaxation was determined as the percentage decrease in basal pressure. This was calculated from the mean anal sphincter pressure before distension to the minimal anal sphincter pressure during the reflex. Duration of the reflex was measured from the onset of the relaxation until the pressure returned to its basal level.

Chemicals
All chemicals were from Sigma (St. Louis, Missouri, USA), unless otherwise stated. The following drugs were used: ATP, L-NAME, suramin, tetrodotoxin, and SNP. All chemicals were dissolved in distilled water and diluted in Krebs-Ringer solution to the stated final concentration.
Statistical analysis

Group data are expressed as mean (SEM). Differences in data were evaluated using the Mann-Whitney U test or the Wilcoxon signed ranks test were indicated. A p value of <0.05 was considered statistically significant. The n values reported refer to the number of animals used in each protocol.

RESULTS

Immunohistochemistry

nNOS-ir in the region of the IAS

In both control (KIT W-lacZ+/+) (not shown) and KIT W-lacZ/KIT w+w mice (fig 1A, B), a dense network of nNOS-ir nerve fibres was present in the circular and longitudinal muscle layers of the distal rectum, including the IAS. Within the intermuscular plane of the IAS, both nNOS-ir neurones and nerve bundles were present but myenteric ganglia contained fewer neurones and the nerve bundles were coarser when compared with the distribution in the proximal rectum (not shown). Conversely, the density of nNOS-ir nerve fibres and neurones of the

Figure 1  Neuronal nitric oxide synthase (nNOS)-ir distribution in the anorectum of a KIT W-lacZ/KIT w+w interstitial cells of Cajal deficient mouse. (A) An 8 μm thick projection of the myenteric region, showing a few nNOS-ir myenteric neurones and numerous large nerve bundles. (B) A 16 μm thick projection of the circular muscle layer and submucosal plexus, showing abundant nNOS-ir nerve fibres in the circular muscle layer and submucosal nNOS-ir fibres and neurones. Orientation: oral, left; aboral, right. Scale bars 50 μm.

Figure 2  Distribution of KIT-ir interstitial cells of Cajal (ICC) in the internal anal sphincter (IAS) region of control KIT W-lacZ/+ and ICC deficient KIT W-lacZ/KIT w+w mice. (A, B) Longitudinal sections across the IAS region of a control KIT W-lacZ/+ mouse (A) and an ICC deficient KIT W-lacZ/KIT w+w mouse (B). The arrows in the lumen indicate mucocutaneous transition. The various populations of KIT-ir ICC are abundant in the control (A) while KIT-ir ICC are essentially lacking in ICC deficient animals (B). (C, D) Whole mount preparations showing KIT-ir ICC in the submucosal plexus of a control KIT W-lacZ/+ mouse (C) and an ICC deficient KIT W-lacZ/KIT w+w mouse (D). KIT-ir ICC form chains running parallel to the circular muscle layer and interconnected by multiple processes in the submucosal plexus of a control KIT W-lacZ/+ mouse (C) while in the submucosal plexus of an ICC deficient KIT W-lacZ/KIT w+w mouse (D) chains of KIT-ir ICC appeared only faintly stained (arrowheads) and lack most longitudinal interconnecting processes. Orientation in (C, D): oral at left, aboral at right. CM, circular muscle layer; LM, longitudinal muscle layer; PF, striated muscle of the pelvic floor. Scale bars 50 μm.

Figure 3  Representative recordings showing the non-adrenergic non-cholinergic inhibitory responses to electrical impulses (0.25–8.0 Hz, 1 ms, pulse trains lasting 10 seconds), 5'-adenosine triphosphate (ATP 1.0 mM), and sodium nitroprusside (SNP 2.5 mM) in muscle strips of a KIT w+w control (A), KIT w+/w w mouse (B), neuronal nitric oxide synthase (nNOS) control (C), and nNOS −/− mouse (D).
submucosal plexus within the region of the IAS was similar to the proximal rectum.

**KIT ir in the region of the IAS**

In controls (fig 2A), spindle shaped KIT ir ICC were present in both muscle layers, parallel to smooth muscle cells. Stellate KIT ir ICC were abundant surrounding the myenteric ganglia. At the level of the submucosal plexus, KIT ir ICC formed chains parallel to the circular muscle layer. These chains were connected to each other by numerous delicate longitudinally processes. ICC at the submucosal plexus exhibited a weaker KIT ir compared with the other populations of KIT ir ICC and were best viewed on whole mounts (fig 2C). In the jejenum of the same animals, KIT ir was detected in ICC-MP and ICC-DMP, as expected (not shown).

In ICC deficient animals mice, KIT ir ICC were lacking in the muscle layers and around the myenteric ganglia (fig 2D) while faint KIT ir ICC at the level of the submucosal plexus were still present (fig 2D). However, they were less abundant and apparently lacked the normal branching pattern (compare with fig 2C). In the jejunum of these animals, a few ICC-DMP exhibited weak KIT ir, as expected in these ICC deficient animals (not shown). Due to the extreme lack of KIT expressing ICC in the region of the IAS of ICC deficient animals, no quantification was attempted.

**Xgal histochemistry in KIT W\(^{\text{W-lacZ}}\)/KIT W\(^{\text{Wv}}\)**

While Xgal histochemistry readily detected nuclei of KIT expressing ICC-DMP in the jejenum, no Xgal deposit was observed in the proximal rectum, or in the region of the IAS (not shown).

**Organ bath studies**

**Involvement of NO in the inhibitory innervation of the IAS**

In the presence of atropine and guanethidine, electrical stimulation (0.25–8.0 Hz, 1 ms, pulse trains lasting 10 seconds) induced a frequency dependent relaxation of circular muscle strips of the murine IAS during the period of stimulation followed by an off contraction (fig 3A, C). Maximal relaxation of KIT W\(^{\text{W/+}}\) controls was obtained at 4 Hz (0.16 (0.05) g) (fig 4A) and in nNOS controls at 2 Hz (0.32 (0.14) g) (fig 4B). The resting (active) tone of the muscle strips of KIT W\(^{\text{W/+}}\) controls (0.5 g), KIT\(^{\text{W/+}}\)/KIT W\(^{\text{Wv}}\) mice (0.5 g), nNOS controls (0.6 g), and nNOS\(^{-/-}\) mice (0.6 g) were comparable.

Both relaxation and the off contraction were abolished by tetrodotoxin, a blocker of neuronal conductance. SNP induced sustained relaxation (0.15 (0.01) g for control mice) of IAS muscle strips. Relaxation to SNP was resistant to tetrodotoxin. In contrast with SNP, ATP failed to relax the IAS preparation (fig 3).

**Effect of L-NAME in control mice**

Inhibition by L-NAME reduced relaxations in KIT W\(^{\text{W/+}}\) controls (n = 8, fig 4A) and in nNOS control mice (n = 6, fig 4B) (p<0.001). L-NAME had no effect on relaxations to SNP. The combination of L-NAME and suramin did not further reduce relaxations (n = 4, p = 0.19) (data not shown).

**Studies in nNOS\(^{-/-}\) mice**

To further evaluate the role of nitricergic neurotransmission in the relaxation of the IAS, mice deficient in nNOS were...
Figure 7 Amplitude of the rectoanal inhibitory reflex (RAIR) in neuronal nitric oxide synthase deficient (nNOS−/−) mice and KIT Wv/− mice is significantly decreased compared with nNOS control mice and KIT Wv/+ control mice (n = 10; p < 0.05, Wilcoxon signed ranks test). Treatment of wild-type mice with N-nitro-L-arginine methyl ester (L-NAME 100 mg/kg intraperitoneally) reduced the occurrence of RAIR to a similar extent. Treatment of KIT Wv/−/KIT Wv+ with L-NAME (100 mg/kg intraperitoneally) slightly reduced the occurrence of RAIR (NS). Values are mean (SEM).

Evaluation of the role of ICC in the inhibitory innervation of the IAS.

We next determined the NANC inhibitory response of IAS tissue of KIT Wv/−/KIT Wv+ mice. Electrical stimulation induced a frequency dependent relaxation of circular muscle strips of the murine IAS during the period of stimulation followed by an off contraction (fig 3D). However, relaxations were also significantly reduced in nNOS−/− deficient mice compared with their controls (n = 6; p < 0.0001) (fig 4B).

Anorectal manometry

Involvement of NO in the inhibitory innervation of the IAS

Basal IAS pressure in KIT W+/+ control mice was 21 (3) mm Hg (n = 10) (fig 5) and 21 (2) mm Hg (n = 10) for nNOS control mice. Distension of the rectum elicited a volume dependent relaxation or RAIR. Both in KIT W+/+ controls (fig 6) and nNOS controls, the duration of the RAIR was independent of distension volume. Mean durations were 14 (1) and 13 (1) seconds, respectively.

Effect of L-NAME in control mice

Administration of intraperitoneal L-NAME to nNOS controls reduced significantly the relaxations (p < 0.05) (fig 7). In KIT W+/+ control mice, a comparable reduction was seen after administration of L-NAME (results not shown).

Studies in nNOS−/− mice

Basal IAS pressure in nNOS−/− mice was comparable to their nNOS controls (21 (3) and 21 (2) mm Hg, respectively). However, the amplitude of the RAIR was significantly lower in nNOS−/− mice compared with nNOS controls (p < 0.01) (figs 6, 7). Notably, the average duration of the RAIR was increased in nNOS−/− mice compared with their controls (24 (3) and 15 (1) seconds, respectively; p < 0.01).

Evaluation of the role of ICC in the inhibitory innervation of the IAS.

Basal IAS pressure in KIT W+/KIT Wv+ was comparable to controls (15 (2) and 21 (3) mm Hg respectively, n = 10) (fig 5). Although the magnitude of the basal pressure was comparable, KIT W+/KIT Wv+ mice showed a more irregular basal sphincter pressure pattern with twitch contractions compared with controls. Distension of the rectum elicited a volume dependent relaxation in KIT W+/KIT Wv+ mice. However, the RAIR amplitude was significantly attenuated in KIT W+/KIT Wv+ mice compared with KIT W+/+ controls (figs 6, 7). At high distension volume, the RAIR could be observed in KIT W+/KIT Wv+ mice although with variable duration and amplitude (figs 6, 7).

Administration of intraperitoneal L-NAME to KIT W+/KIT Wv+ mice had no effect (fig 7).

Compliance in KIT W+/+ control mice and in KIT W+/KIT Wv+ mice

As the differences in RAIR could result from changes in rectal compliance, we also determined this parameter in both control and KIT W+/KIT Wv+ mice. Stepwise rectal volume distension revealed a similar increase in rectal pressure, demonstrating that rectal compliance was similar in control and KIT W+/KIT Wv+ mice (fig 8).

DISCUSSION

NO is recognised as an important inhibitory neurotransmitter in the IAS. Previous studies showed that blockade of NO biosynthesis reduced the relaxation of muscle strips of the IAS elicited by electrical stimulation and impaired the RAIR. In the present study, we extended the role of NO as an inhibitory neurotransmitter to the murine IAS: blockade of NO biosynthesis resulted in a reduction of both the in vitro and in vivo relaxation of the IAS. These findings were further corroborated by experiments in nNOS−/− mice. Isolated muscle strips relaxed significantly less whereas the RAIR was impaired compared with controls. It should be emphasised that the IAS still relaxed in nNOS−/− mice and that blockade of NO biosynthesis in controls incompletely...
reduced electrical stimulation induced relaxation. These observations suggest that either nitrergic blockade was incomplete or, most likely, that another inhibitory neurotransmitter is involved. Previous studies in the rat IAS suggested ATP as a possible candidate.7 However, in our study, high concentrations of ATP failed to relax the IAS. In addition, suramin had no effect on relaxation, excluding the possible involvement of ATP. To what extent vasoactive intestinal polypeptide is involved remains to be investigated.5

ICC have been suggested to play a crucial role in normal gastrointestinal motility. In addition to their role as pacemaker cells,15 16 previous studies have suggested that ICC function as an intermediate between nerve fibres and smooth muscle cells mediating the nitrergic inhibitory neurotransmission in the stomach, LOS, and pyloric sphincter.14 15 Due to the absence of the intramuscular-type of ICC, LOS muscle strips from KITWvKITWv mice contracted rather than relaxed in response to electrical stimulation.7 Administration of L-NAME did not further change the response.7 As immunohistochemistry staining showed that the nitrergic innervation was intact, these findings indicated that ICC are important mediators of the nitrergic innervation in these tissues. In the present study, we failed to confirm this observation in the IAS. Electrical stimulation of the IAS of KITWvKITWv mice relaxed to the same extent as those from controls. In addition, blockade of NO biosynthesis greatly reduced these relaxations, indicating that nitrergic innervation was intact. The latter was further confirmed by immunohistochemical staining. Our results argue against a role for ICC, as intermediate between nitrergic nerves and smooth muscle cells. A similar conclusion was drawn by Sivarao and colleagues19 who showed that relaxations of the LOS in response to swallowing or vaginal stimulation was unaffected in KITWvKITWv mice.

How can the discrepancy between our data and those of Ward and colleagues7 be explained? One could argue that the electrical stimulation parameters used (1 ms) were too intense, resulting in overflow of NO to the smooth muscle which might still elicit responses in tissue lacking ICC.20 However, in preliminary experiments, electrical stimulation with pulse trains of 0.5 ms failed to relax the IAS significantly. Furthermore, 1 ms pulse trains resulted in a normal frequency dependent response curve, excluding this possibility. Another explanation could be that the network of ICC of the IAS in contrast with the LOS and pylorus is unaffected in KITWvKITWv mice. However, similar to Ward et al, immunohistochemical assessment revealed that in KITWvKITWv and KITWvKITWv mice, KIT-ir ICC were completely lacking in the muscle layers and around the myenteric ganglia.7 Alternatively, regional differences in the distance between nerve varicosities and smooth muscle cells, or differences in sensitivity of smooth muscle cells to NO, could be involved, but clearly this needs to be explored further.

Although we showed that the inhibitory innervation of the IAS in vitro was intact in ICC deficient mice, relaxation of the IAS in response to rectal distension was clearly diminished in KITWvKITWv mice. As it is not clear whether stretch or tension receptors are involved in the triggering of the RAIR, one might argue that changes in compliance could affect the IAS response to rectal distension. Rectal compliance in ICC deficient mice was however identical to that of control mice. This is in contrast with Ward et al who described changes in gastric compliance in ICC deficient mice.21 This discrepancy can be explained by the fact that in the stomach, ICC have been shown to be involved in nitrergic and cholineric neurotransmission, most likely contributing to the described changes in compliance in mice lacking ICC. In our experiments, however, we were unable to confirm the involvement of ICC in the nitrergic neurotransmission of the IAS, which may explain why compliance in the anorectal area is not altered. Our finding that the RAIR is strongly diminished in KITWvKITWv mice in the presence of an unaltered rectal compliance suggests the involvement of ICC in the triggering of the RAIR.

Theoretically, ICC could play a role in the neural pathway mediating the RAIR, either at the afferent limb in the detection of rectal distension or at the efferent part23 by mediating nitrergic neurotransmission.22 Our data favour involvement of ICC in the afferent limb, as both immunohistochemical and in vitro studies showed normal nitrergic neurotransmission in the IAS of KITWvKITWv mice. One possible explanation could be that ICC act as mechanoreceptors detecting rectal distension. Previous studies indeed showed that ICC make direct functional contact with intramuscular arrays of enteric nerves18 22 and therefore could be involved in mechanical perception of distension. Alternatively, ICC may be required for the development of afferent nerves, especially as intramuscular arrays of vagal afferent fibres are significantly reduced in density in KITWvKITWv mice compared with controls. This would suggest that abnormalities in the afferents secondary to the absence of a normal ICC network would underlie the impaired detection of stretch. However, the RAIR is considered to be mediated by a neural circuitry located within the enteric nervous system and, so far, no abnormalities in the enteric sensory neurones have been described in ICC deficient mice. To what extent the RAIR is impaired in KITWvKITWv mice secondary changes in intrinsic sensory neurones or whether the ICC function as mechanoreceptors cannot be determined from our experiments.

Impaired or absent relaxation of the IAS hampers the evacuation of stool leading to severe chronic constipation.4 The typical example is Hirschsprung’s disease characterised by aganglionosis of the distal gastrointestinal tract with subsequent absence of the RAIR and delayed passage of meconium. Similarly, delayed evacuation of meconium is also present in another subgroup of neonates with abdominal distension and feeding problems.24 However, gastrointestinal symptoms resolve soon after birth. The exact reason for this delayed evacuation of meconium is unclear. Interestingly, a study showed that delayed maturation of ICC may lead to the development of defecation problems in neonates.25 As we showed that a deficiency of ICC impairs the RAIR, delayed maturation of ICC could be involved in the delayed passage of meconium in neonates. This hypothesis is currently being investigated.

In conclusion, we showed that the inhibitory innervation of the IAS and the RAIR are mediated by NO. Moreover, a normal RAIR requires an intact network of ICC in the IAS. Thus both loss of nitrergic innervation and deficiency of ICC lead to impaired anal relaxation and may play an important role in rectal evacuation disorders.

A 59 year old man was referred with a one year history of change in bowel habit and a low folate level. He had been opening his bowels more frequently but there was no associated abdominal pain or weight loss. Previous medical history included uveitis. Medication consisted of folic acid and he smoked 40 cigarettes a day. Physical examination was unremarkable. Initial blood tests revealed a normal full blood count, urea and electrolytes, liver and thyroid function, glucose, and C reactive protein A double contrast barium enema was performed (fig 1).

Question
In fig 1, what abnormality is demonstrated and what diagnostic procedure was then performed?
