On an identity by Chaundy and Bullard. I

Tom H. Koornwinder and Michael J. Schlosser

Dedicated to Richard Askey on the occasion of his 75th birthday

Abstract

An identity by Chaundy and Bullard writes $1/(1-x)^n$ ($n = 1, 2, \dots$) as a sum of two truncated binomial series. This identity was rediscovered many times. Notably, a special case was rediscovered by I. Daubechies, while she was setting up the theory of wavelets of compact support. We discuss or survey many different proofs of the identity, and also its relationship with Gauß hypergeometric series. We also consider the extension to complex values of the two parameters which occur as summation bounds. The paper concludes with a discussion of a multivariable analogue of the identity, which was first given by Damjanovic, Klamkin and Ruehr. We give the relationship with Lauricella hypergeometric functions and corresponding PDE's. The paper ends with a new proof of the multivariable case by splitting up Dirichlet's multivariable beta integral.

1 Introduction

Chaundy and Bullard noted “in passing” the identity

$$1 = (1-x)^{n+1} \sum_{k=0}^m \binom{n+k}{k} x^k + x^{m+1} \sum_{k=0}^n \binom{m+k}{k} (1-x)^k, \quad (1.1)$$

as a side result in their 1960 paper *John Smith's problem*, see [3, p.256]. Here m, n are nonnegative integers. Formula (1.1) can be written more succinctly as

$$p_{m,n}(x) + p_{n,m}(1-x) = 1, \quad (1.2)$$

where

$$p_{m,n}(x) := (1-x)^{n+1} \sum_{k=0}^m \binom{n+k}{k} x^k = (1-x)^{n+1} \sum_{k=0}^m \frac{(n+1)_k}{k!} x^k \quad (1.3)$$

and

$$(a)_k := \begin{cases} a(a+1) \dots (a+k-1) & \text{if } k = 1, 2, \dots, \\ 1 & \text{if } k = 0, \end{cases} \quad (1.4)$$

is the *Pochhammer symbol*.

The Chaundy-Bullard identity (1.1) was rediscovered (partially or completely) many times:

- In 1971 Herrmann [9] interpreted $p_{m,n}(x)$ (see (1.3)) as the polynomial of degree $m+n+1$ which has a zero of order $n+1$ at $x=1$ and such that $1-p_{m,n}(x)$ has a zero of order $m+1$ at $x=0$. He proved this by induction with respect to n (although we think that he meant induction with respect to $m+n$). Essentially, although not explicitly given in [9], Herrmann's result implies the identity (1.2).
- The identity (1.1) was proposed in 1975 for the Canadian Mathematical Olympiad (but not used there). Next it was proposed in 1976 for the problem section of *Crux Mathematicorum*. A proof by induction by Kleiman was given there [15] in 1977. The same identity was also proposed in 1977 for the elementary problem section in the *American Mathematical Monthly* by Burman. The *Monthly* [16] gave two solutions in 1979, one probabilistic proof by Schmitt and one using partial fractions by Jagers. Much later, in 1992 in the *Monthly* [18] the probabilistic proof was implicit in the solution of a problem about the longest expected world series, posed in 1990 by Schuster. In 1997 the *Monthly* [19] had a follow-up with some non-probabilistic proofs.
- A two-variable analogue of the identity (1.1) was proposed in 1985 for the problem section in *SIAM Review* by Klamkin & Ruehr. In 1986 Bosch & Steutel gave in this journal [17] a probabilistic proof as solution. In [17] it was also observed by Damjanovic, Klamkin & Ruehr that there is an n -variable generalization of the identity:

$$\sum_{i=1}^n x_i \sum_{k_1=0}^{a_1} \cdots \sum_{k_n=0}^{a_n} \delta_{k_i, a_i} \frac{(k_1 + \cdots + k_n)!}{k_1! \cdots k_n!} x_1^{k_1} \cdots x_n^{k_n} = 1 \quad (x_1 + \cdots + x_n = 1). \quad (1.5)$$

They gave a proof by generating functions. A probabilistic proof was also indicated.

- In 1988 Daubechies [4, Lemma 4.4], see also [5, (6.1.7), (6.1.12)], rediscovered the case $m=n$ of (1.1). This identity was a crucial step for her in order to arrive at the form of the function $m_0(\xi)$ which is associated with the wavelets of compact support named after her. Her proof in [5] was essentially the same as Jagers' proof in [16], but she referred to Bézout's identity. Next Zeilberger [22] in 1993 gave a probabilistic proof of Daubechies' case $m=n$ of (1.1) and, unaware of [17], he stated the case $a_1 = \cdots = a_n$ of (1.5) and indicated a probabilistic proof.
- Multiplication of both sides of (1.1) by $(1-x)^{-n-1}$ gives

$$(1-x)^{-n-1} = \sum_{k=0}^m \frac{(n+1)_k}{k!} x^k + x^{m+1} \sum_{k=0}^n \frac{(m+1)_k}{k!} (1-x)^{k-n-1}. \quad (1.6)$$

This identity is the case $m=0$ of the identity at the end of section 8 in Vidūnas [21], where it is given as a three-term identity for three Gauß hypergeometric functions satisfying the same hypergeometric differential equation in the most degenerate case (trivial monodromy group).

- It was also essentially identity (1.6) which was rediscovered by Pieter de Jong (Netherlands), who is studying the mathematical foundations of architecture. It was by his communication to the first author in 2007 that we first became aware of this identity. See also de Jong's manuscript [10].

It is not without precedents in mathematics, in particular in special function theory, that a relatively elementary result is rediscovered and published many times. We think that for (1.1) the elegance and unexpectedness of the identity arose people's interest again and again, as it did with us. Why then spend again a publication on it? First it seems useful to survey all earlier (as far as we know now) occurrences and approaches. Second, we can offer some approaches which did not yet occur, notably the approach by splitting up the beta integral and the context of the Gauß hypergeometric function. Third the possible generalizations are interesting. As we mentioned, the n -variable generalizations already occurred, but we can offer yet unexplored aspects of it. There are also various analogues and generalizations of (1.1) in the q -case, which we will present in a forthcoming paper.

The following sections present or survey many different proofs of (1.1). The proof in section 2 is the original proof by Chaundy and Bullard [3], and its slight variations by Daubechies [5, §6.1] and Jagers [16] are also discussed there. The proof in section 3 is by induction with respect to $m + n$. The proof in section 4 is by repeated differentiation of (4.1) (a method suggested by Pieter de Jong in an earlier version of [10]). The proof in section 5 uses generating functions. It was communicated to us by Helmut Prodinger and it is also a one-variable specialization of a proof in [17]. Another proof of combinatorial flavour in section 6 uses weighted lattice paths, and becomes by specialization a probabilistic proof (different in formulation but in essence the same as many earlier proofs which appeared). Section 7 gives a proof by splitting up the beta integral. In section 8 we consider the extension of (1.1) to complex values of m, n . In section 9 we observe that the three terms in the identity (1.6) all solve a very special (degenerate) case of the hypergeometric differential equation. Next we obtain (1.6) as a limit case of a more general three-term identity for hypergeometric functions, where the three terms all solve a hypergeometric differential equation.

Section 10 starts our discussion of the multivariable analogue (1.5), which was first obtained in [17]. A connection with Appell and Lauricella hypergeometric functions is made. In section 11 a partial differential equation satisfied by all terms in this multivariable analogue is given. Finally we give in section 12 a proof of (1.5) by splitting up Dirichlet's multivariable beta integral (generalizing the approach in section 7).

Acknowledgements We thank Pieter de Jong for showing us his identity and suggesting the proof in section 4, Peter Paule for suggesting the approach with a multivariable beta integral in section 12, and Mike Keane, Oleg Ogievetsky and Helmut Prodinger for helpful remarks.

The second author was partly supported by FWF Austrian Science Fund grants P17563-N13, and S9607 (the latter is part of the Austrian National Research Network "Analytic Combinatorics and Probabilistic Number Theory").

Notation The *Gauß hypergeometric series* (see [1, Ch. 2]) is defined by

$${}_2F_1\left(\begin{matrix} a, b \\ c \end{matrix}; z\right) := \sum_{k=0}^{\infty} \frac{(a)_k (b)_k}{(c)_k k!} z^k \quad (z, a, b, c \in \mathbb{C}, |z| < 1, c \notin \{0, -1, -2, \dots\}), \quad (1.7)$$

where the Pochhammer symbol is given by (1.4). In the *terminating* case we have

$${}_2F_1\left(\begin{matrix} -n, b \\ c \end{matrix}; z\right) := \sum_{k=0}^n \frac{(-n)_k (b)_k}{(c)_k k!} z^k \quad (z, b, c \in \mathbb{C}, n = 0, 1, 2, \dots, c \neq 0, -1, \dots, -n+1). \quad (1.8)$$

2 Chaundy & Bullard's original proof

Fix m and n . By the binomial theorem we have

$$(x + y)^{m+n+1} = y^{n+1}P_{m,n}(x, y) + x^{m+1}P_{n,m}(y, x), \quad (2.1)$$

where

$$P_{m,n}(x, y) := \sum_{k=0}^m \binom{m+n+1}{k} x^k y^{m-k}. \quad (2.2)$$

is a homogeneous polynomial of degree m . Put $y := 1 - x$. Then

$$1 = (1 - x)^{n+1}P_{m,n}(x, 1 - x) + x^{m+1}P_{n,m}(1 - x, x), \quad (2.3)$$

and multiplication by $(1 - x)^{-n-1}$ yields

$$(1 - x)^{-n-1} = P_{m,n}(x, 1 - x) + x^{m+1}(1 - x)^{-n-1}P_{n,m}(1 - x, x). \quad (2.4)$$

Expand both sides of (2.4) as a power series in x , convergent for $|x| < 1$. Then $P_{m,n}(x, 1 - x)$ is a polynomial of degree $\leq m$ in x and all terms in the power series of $x^{m+1}(1 - x)^{-n-1}P_{n,m}(1 - x, x)$ have degree $\geq m + 1$. Hence $P_{m,n}(x, 1 - x)$ equals the power series of $(1 - x)^{-n-1}$ truncated after the term of x^m , i.e.,

$$P_{m,n}(x, 1 - x) = \sum_{k=0}^m \frac{(n+1)_k}{k!} x^k. \quad (2.5)$$

Then substitution of (2.5) in (2.3) proves (1.1), and its homogeneous form

$$(x + y)^{m+n+1} = y^{n+1} \sum_{k=0}^m \frac{(n+1)_k}{k!} x^k (x + y)^{m-k} + x^{m+1} \sum_{k=0}^n \frac{(m+1)_k}{k!} y^k (x + y)^{n-k}. \quad (2.6)$$

Note that, conversely, (1.1) implies (2.5), i.e., the equality

$$\sum_{k=0}^m \binom{m+n+1}{k} x^k (1 - x)^{m-k} = \sum_{k=0}^m \binom{n+k}{k} x^k. \quad (2.7)$$

Indeed, compare (1.6) with (2.4). It was essentially this identity (2.7) which was also stated by Guenther [14] in a comment to the solution of a problem in the Monthly. He pointed out many relationships of this identity with the binomial and negative binomial distribution, including a probabilistic proof.

Remark 2.1. We can rewrite (2.7) as

$$\sum_{k=0}^m \frac{(n+1)_k}{k!} x^k = (1 - x)^m \sum_{k=0}^m \frac{(-m - n - 1)_k}{k!} \left(\frac{x}{x-1}\right)^k.$$

In terms of terminating Gauß hypergeometric series (1.8) this can be written as

$${}_2F_1\left(\begin{matrix} -m, n+1 \\ -m \end{matrix}; x\right) = (1 - x)^m {}_2F_1\left(\begin{matrix} -m, -m - n - 1 \\ -m \end{matrix}; \frac{x}{x-1}\right), \quad (2.8)$$

which is the limit case $a := -m$, $b := n + 1$, $c \rightarrow -m$ of Pfaff's transformation formula

$${}_2F_1\left(\begin{matrix} a, b \\ c \end{matrix}; x\right) = (1-x)^{-a} {}_2F_1\left(\begin{matrix} a, c-b \\ c \end{matrix}; \frac{x}{x-1}\right), \quad (2.9)$$

see [1, (2.2.6)].

Remark 2.2. For the proof of (1.1) from (2.3) as given above, one may start with a weaker form of (2.3) as follows:

$$1 = (1-x)^{n+1}q_{m,n}(x) + x^{m+1}r_{m,n}(x), \quad (2.10)$$

where $q_{m,n}(x)$ and $r_{m,n}(x)$ are polynomials of degree $\leq m$ respectively $\leq n$, so not yet necessarily explicitly given. Since $(1-x)^{n+1}$ and x^{m+1} are polynomials without common zeros of degree $n+1$ respectively $m+1$, we can recognize (2.10) as a *Bézout identity*, where $q_{m,n}(x)$ and $r_{m,n}(x)$ will uniquely exist as polynomials of precise degree m respectively n (see for instance [5, Theorem 6.1.1]). It was in this way that Daubechies [5, §6.1], in the symmetric case $m = n$, proved (1.1). Also note that the symmetry of (2.10) together with the uniqueness and degree properties of $q_{m,n}(x)$ and $r_{m,n}(x)$ already imply that $q_{m,n}(x) = r_{n,m}(1-x)$, without explicit computation.

Equivalent to the Bézout identity approach, (2.10) can be seen as a partial fraction decomposition

$$\frac{1}{x^{m+1}(1-x)^{n+1}} = \frac{q_{m,n}(x)}{x^{m+1}} + \frac{r_{m,n}(x)}{(1-x)^{n+1}}$$

with $q_{m,n}(x)$ and $r_{m,n}(x)$ of degree $\leq m$ respectively $\leq n$, cf. Jagers' proof of (1.1) in [16].

3 A proof by induction

The following proof by induction was essentially given earlier by Kleiman [15] and, for $m = n$, by Daubechies [4, Lemma 4.4]. We have to prove (1.2), with $p_{m,n}(x)$ given by (1.3). First note that (1.2) holds for $n = 0$, and hence, by symmetry, also for $m = 0$. Indeed,

$$p_{m,0}(x) = (1-x) \sum_{k=0}^m x^k = (1-x) \frac{1-x^{m+1}}{1-x} = 1-x^{m+1},$$

and $p_{0,m}(1-x) = x^{m+1}$, so $p_{m,0}(x) + p_{0,m}(1-x) = 1$.

Now we prove (1.2) by induction with respect to $m+n$. We already saw that it holds for $m+n=0$, i.e., for $m=n=0$. Now suppose that (1.2) holds for all m, n with $m+n = N-1$. Let $m+n = N$. Then we already proved (1.2) if $m=0$ or $n=0$, so we may assume that $m, n > 0$. Substitute the recurrence relation

$$\binom{n+k}{k} = \binom{n+k-1}{k-1} + \binom{n+k-1}{k}$$

for binomial coefficients into (1.3). Then

$$p_{m,n}(x) = (1-x)^{n+1} \sum_{k=1}^m \binom{n+k-1}{k-1} x^k + (1-x)^{n+1} \sum_{k=0}^m \binom{n+k-1}{k} x^k$$

$$\begin{aligned}
&= x(1-x)^{n+1} \sum_{l=0}^{m-1} \binom{n+l}{l} x^l + (1-x)p_{m,n-1}(x) \\
&= xp_{m-1,n}(x) + (1-x)p_{m,n-1}(x).
\end{aligned} \tag{3.1}$$

Hence

$$p_{n,m}(1-x) = xp_{n,m-1}(1-x) + (1-x)p_{n-1,m}(1-x). \tag{3.2}$$

Adding (3.1) and (3.2) gives

$$\begin{aligned}
p_{m,n}(x) + p_{n,m}(1-x) &= x(p_{m-1,n}(x) + p_{n,m-1}(1-x)) + (1-x)(p_{m,n-1}(x) + p_{n-1,m}(1-x)) \\
&= x + (1-x) = 1
\end{aligned}$$

by induction. This completes the proof of (1.2).

4 A proof by repeated differentiation

Here we give a proof of (1.6) which was sketched by Pieter de Jong in an earlier version of [10]. First note that the case $n = 0$ of (1.6) is evident. It is essentially the summation formula for the terminating geometric series:

$$\frac{1}{1-x} = 1 + x + x^2 + \cdots + x^m + \frac{x^{m+1}}{1-x}. \tag{4.1}$$

Now we can prove (1.6) by induction with respect to n (for each n for general m). For $n = 0$ we have (4.1), which is evident. Apply the operator $(n+1)^{-1}d/dx$ to both sides of (1.6). The left-hand side becomes $(1-x)^{-n-2}$, the right-hand side becomes

$$\sum_{k=0}^{m-1} \frac{(n+2)_k}{k!} x^k + x^m \sum_{k=0}^n \frac{m+1}{n+1} \frac{(m+1)_k}{k!} (1-x)^{k-n-1} + x^{m+1} \sum_{k=0}^n \frac{n-k+1}{n+1} \frac{(m+1)_k}{k!} (1-x)^{k-n-2}.$$

So we will have proved (1.6) with n replaced by $n+1$ and m replaced by $m-1$ if we can show that

$$x^m \sum_{k=0}^n \frac{m+1}{n+1} \frac{(m+1)_k}{k!} (1-x)^{k-n-1} + x^{m+1} \sum_{k=0}^n \frac{n-k+1}{n+1} \frac{(m+1)_k}{k!} (1-x)^{k-n-2} \tag{4.2}$$

is equal to

$$x^m \sum_{k=0}^{n+1} \frac{(m)_k}{k!} (1-x)^{k-n-2}. \tag{4.3}$$

In order to show this, rewrite x^{m+1} in the second term of (4.2) as $x^{m+1} = x^m - x^m(1-x)$, by which (4.2) becomes

$$x^m \sum_{k=0}^n \frac{m-n+k}{n+1} \frac{(m+1)_k}{k!} (1-x)^{k-n-1} + x^m \sum_{k=0}^n \frac{n-k+1}{n+1} \frac{(m+1)_k}{k!} (1-x)^{k-n-2}$$

$$\begin{aligned}
&= x^m \sum_{k=1}^{n+1} \frac{m-n+k-1}{n+1} \frac{(m+1)_{k-1}}{(k-1)!} (1-x)^{k-n-2} + x^m \sum_{k=0}^n \frac{n-k+1}{n+1} \frac{(m+1)_k}{k!} (1-x)^{k-n-2} \\
&= x^m (1-x)^{-n-2} + x^m \sum_{k=1}^n \frac{(m)_k}{k!} (1-x)^{k-n-2} + \frac{(m)_{n+1}}{(n+1)!} x^m (1-x)^{-1},
\end{aligned}$$

which equals (4.3). This completes the induction step.

5 A proof by generating functions

In [17] a proof by generating functions was given for the n -variable generalization (1.5) of (1.1). Of course this proof can be specialized to a proof by generating functions of (1.1). Such a proof of (1.1) was also communicated to us by Helmut Prodinger, independently from [17]. Because the one-variable case is more simple, we give the proof here.

Fix $x \in (0, 1)$. For $u, v \in (0, 1)$ let

$$f(u, v; x) := \sum_{m, n \geq 0} u^m v^n (1-x)^{n+1} \sum_{k=0}^m \binom{n+k}{k} x^k. \quad (5.1)$$

Then

$$f(v, u; 1-x) = \sum_{m, n \geq 0} u^m v^n x^{m+1} \sum_{k=0}^n \binom{m+k}{k} (1-x)^k. \quad (5.2)$$

From (5.1) we have

$$\begin{aligned}
f(u, v; x) &= \frac{1}{1-u} \sum_{n \geq 0} v^n (1-x)^{n+1} \sum_{k \geq 0} \binom{n+k}{k} (ux)^k \\
&= \frac{1}{1-u} \sum_{n \geq 0} v^n (1-x)^{n+1} \frac{1}{(1-ux)^{n+1}} \\
&= \frac{1-x}{(1-u)(1-ux)} \frac{1}{1 - \frac{v(1-x)}{1-ux}} \\
&= \frac{1-x}{1-u} \frac{1}{1-ux-v(1-x)}.
\end{aligned}$$

Hence

$$f(v, u; 1-x) = \frac{x}{1-v} \frac{1}{1-ux-v(1-x)}$$

and

$$f(u, v; x) + f(v, u; 1-x) = \frac{1}{1-ux-v(1-x)} \left(\frac{1-x}{1-u} + \frac{x}{1-v} \right) = \frac{1}{(1-u)(1-v)}.$$

So

$$f(u, v; x) + f(v, u; 1-x) = \sum_{m, n \geq 0} u^m v^n,$$

and combined with (5.1), (5.2) this yields (1.1) by taking the coefficient of $u^m v^n$.

6 A proof by weighted lattice paths

Consider all lattice paths from $(0, 0)$ to $(m + 1, n + 1)$ in the planar integer lattice (using only unit east and north steps). Such a path P consists of $m + n + 2$ successive unit steps $s_k(P)$ ($k = 1, 2, \dots, m + n + 2$). Let P_k be the path P terminated after k steps. The weight $w(P)$ of a path P is defined to be the product of the weight of the respective steps s of the path, i.e., $w(P) = \prod_{s \in P} w(s)$. Define the weight function w as follows:

$$w((i, j) \rightarrow (i + 1, j)) := \begin{cases} x & (j < n + 1), \\ x + y & (j = n + 1), \end{cases}$$

$$w((i, j) \rightarrow (i, j + 1)) := \begin{cases} y & (i < m + 1), \\ x + y & (i = m + 1). \end{cases}$$

Since for each $k \in \{1, \dots, m + n + 2\}$ and for each truncated path P_{k-1} we have

$$\sum_{P_k; P_k \setminus s_k(P_k) = P_{k-1}} w(s_k(P_k)) = x + y,$$

we find by induction that $\sum_{P_k} w(P_k) = (x + y)^k$, and hence

$$\sum_P w(P) = (x + y)^{m+n+2}. \quad (6.1)$$

On the other hand each path P ends either with a vertical step or with a horizontal step. Consider first the paths which end with a vertical step. Then the last horizontal step will be $(m, k) \rightarrow (m + 1, k)$ for some $k \in \{0, 1, \dots, n\}$. For given k all such paths have weight $x^{m+1}y^k(x + y)^{n-k+1}$ and the number of such paths is $\binom{m+k}{k}$. Hence the sum of the weights of all paths which end with a vertical step equals

$$x^{m+1} \sum_{k=0}^n \binom{m+k}{k} y^k (x + y)^{n-k+1}. \quad (6.2)$$

Similarly, the sum of the weights of all paths which end with a horizontal step equals

$$y^{n+1} \sum_{k=0}^m \binom{n+k}{k} x^k (x + y)^{m-k+1}. \quad (6.3)$$

Since (6.1) = (6.2) + (6.3), we have obtained (2.6) with both sides multiplied by $x + y$.

Remark 6.1. For $0 \leq x \leq 1$ and $y := 1 - x$ we can give a probabilistic interpretation of the above results. Now consider all lattice paths from $(0, 0)$ to $(m + 1, n + 1)$, where each following step has probability 1 if there is only one possible step, and otherwise probability x if the step is horizontal and $1 - x$ if it is vertical. Then (6.2) gives the probability that the last step is vertical and (6.3) the probability that the last step is horizontal, and the sum of both probabilities is necessarily 1. Thus we have a probabilistic proof of (1.1).

Many probabilistic proofs of (1.1) were earlier given, see [16], [18], [22]. They are essentially all equivalent to the one given in the previous paragraph. Zeilberger's [22] proof (phrased by him for $m = n$) is particularly succinct. For general m, n it reads as follows:

Toss a coin (with $Pr(head) = x$) until reaching $m + 1$ heads or $n + 1$ tails. Then equate the probability, 1, of finishing after at most $m + n + 1$ tossings with the sum of the probabilities of all the final outcomes. This yields (1.1).

7 A proof using the beta integral

By the evaluation of the beta integral (see [1, §1.1]) we have for $x \in (0, 1)$:

$$\begin{aligned} 1 &= \frac{(m+n+1)!}{m!n!} \int_0^1 t^m(1-t)^n dt \\ &= \frac{(m+n+1)!}{m!n!} \int_0^x t^m(1-t)^n dt + \frac{(m+n+1)!}{m!n!} \int_x^1 t^m(1-t)^n dt \\ &= \frac{(m+n+1)!}{m!n!} \int_0^x t^m(1-t)^n dt + \frac{(m+n+1)!}{m!n!} \int_0^{1-x} t^n(1-t)^m dt. \end{aligned} \quad (7.1)$$

Then (1.1) will follow from (7.1) if we can prove that

$$\frac{(m+n+1)!}{m!n!} \int_0^x t^m(1-t)^n dt = x^{m+1} \sum_{k=0}^n \frac{(m+1)_k}{k!} (1-x)^k. \quad (7.2)$$

But (7.2) follows by the string of equalities

$$\begin{aligned} \int_0^x t^m(1-t)^n dt &= x^{m+1} \int_0^1 s^m(1-s+s(1-x))^n ds \\ &= x^{m+1} \sum_{k=0}^n \binom{n}{k} (1-x)^k \int_0^1 s^{m+k}(1-s)^{n-k} ds = \frac{m!n!x^{m+1}}{(m+n+1)!} \sum_{k=0}^n \frac{(m+1)_k}{k!} (1-x)^k. \end{aligned}$$

The integral on the left-hand side of (7.2) is an *incomplete beta function*, which is usually expressed as a hypergeometric function (1.7) (see [7, §2.5.3, p.87], also for m, n complex with $\operatorname{Re} m > -1$):

$$B_x(m+1, n+1) := \int_0^x t^m(1-t)^n dt = \frac{1}{m+1} x^{m+1} {}_2F_1\left(\begin{matrix} -n, m+1 \\ m+2 \end{matrix}; x\right) \quad (x \in (0, 1)). \quad (7.3)$$

The proof of (7.3) is by binomial expansion of $(1-t)^n$. Then (7.1) takes the form

$$\begin{aligned} 1 &= \frac{\Gamma(n+m+2)}{\Gamma(m+1)\Gamma(n+1)} B_x(m+1, n+1) + \frac{\Gamma(n+m+2)}{\Gamma(m+1)\Gamma(n+1)} B_{1-x}(n+1, m+1) \\ &\quad (x \in (0, 1), m, n \in \mathbb{C}, \operatorname{Re} m, \operatorname{Re} n > -1). \end{aligned} \quad (7.4)$$

The right-hand side of (7.2) can be written as a terminating hypergeometric series (1.8). Then combination of (7.2) and (7.3) yields

$$x^{m+1} {}_2F_1\left(\begin{matrix} -n, m+1 \\ -n \end{matrix}; 1-x\right) = \frac{(m+n+1)!}{(m+1)!n!} x^{m+1} {}_2F_1\left(\begin{matrix} -n, m+1 \\ m+2 \end{matrix}; x\right). \quad (7.5)$$

Alternatively, (7.5) can be proved as the limit case for $c \rightarrow -n$ of *Pfaff's identity*

$${}_2F_1\left(\begin{matrix} -n, b \\ c \end{matrix}; 1-x\right) = \frac{(c-b)_n}{(c)_n} {}_2F_1\left(\begin{matrix} -n, b \\ b-c-n+1 \end{matrix}; x\right) \quad (n \text{ nonnegative integer}), \quad (7.6)$$

see [1, (2.3.14)].

8 Extension of the identity to non-integer m and n

By (7.2), (7.3) the formula

$$p_{m,n}(x) = \frac{\Gamma(m+n+2)}{\Gamma(m+1)\Gamma(n+1)} B_{1-x}(n+1, m+1) \quad (x \in (0, 1), m, n \in \mathbb{C}, \operatorname{Re} n > -1) \quad (8.1)$$

extends (1.3) to non-integer values of m, n . Then, by (7.4), the identity (1.2) holds for $x \in (0, 1)$ and $m, n \in \mathbb{C}$ with $\operatorname{Re} m, \operatorname{Re} n > -1$ if $p_{m,n}(x)$ is given by (8.1). Moreover, by Carlson's theorem (see for instance Titchmarsh [20, §5.81]) this is the unique extension

$$p_{m,n}(x) + q_{m,n}(x) = 1 \quad (x \in (0, 1), m, n \in \mathbb{C}, \operatorname{Re} m, \operatorname{Re} n > -1)$$

of (1.2) such that for nonnegative integer m, n we have $p_{m,n}(x) = q_{n,m}(1-x)$ given by (7.2), $p_{m,n}(x)$ and $q_{m,n}(x)$ are analytic in m, n for $\operatorname{Re} m, \operatorname{Re} n > -1$ with x fixed, and $p_{m,n}(x)$ and $q_{m,n}(x)$ satisfy, for some $c \in (0, \pi)$, estimates $O(e^{c|m|})$ and $O(e^{c|n|})$ as $\operatorname{Re} m, \operatorname{Re} n \geq 0$. Indeed, fix m with $\operatorname{Re} m > -1$ and $x \in (0, 1)$. Then, in the right-hand side of (8.1) we have for $\operatorname{Re} n \geq 0$:

$$|B_{1-x}(n+1, m+1)| \leq B_{1-x}(\operatorname{Re} n + 1, \operatorname{Re} m + 1) \leq \int_0^{1-x} (1-t)^{\operatorname{Re} m} dt = \frac{(1-x)^{\operatorname{Re} m+1}}{\operatorname{Re} m + 1}$$

and (as a consequence of the asymptotic formula for $\Gamma(z)$, see [1, Theorem 1.4.1])

$$\left| \frac{\Gamma(m+n+2)}{\Gamma(m+1)\Gamma(n+1)} \right| = O(|n|^{\operatorname{Re} m+1}).$$

Hence, for x, m fixed as above, the right-hand side of (8.1) is $O(e^{c|n|})$ as $\operatorname{Re} n \geq 0$ for arbitrary small $c > 0$. We can estimate the other cases in a similar way.

Alternatively, we may write (1.3) as

$$p_{m,n}(x) = (1-x)^{n+1} \sum_{k=0}^m \frac{\Gamma(n+k+1)}{\Gamma(n+1)\Gamma(k+1)} x^k. \quad (8.2)$$

Consider (8.2) for $x \in (0, 1)$ and $n \in \mathbb{C}$ with $\operatorname{Re} n > -1$, and then try on it the fractional extension of finite sums proposed by Müller & Schleicher [11], [12]. Since for $k \in \mathbb{C}$ with $\operatorname{Re} k \geq 0$ we have

$$f(k) := \frac{\Gamma(n+k+1)}{\Gamma(n+1)\Gamma(k+1)} x^k (1-x)^{n+1} = o(1) \quad \text{as } \operatorname{Re} k \rightarrow \infty,$$

their recipe of fractional extension (see [11, (10)], [12, top of p.5]) of the sum $\sum_{k=0}^m f(k)$ is

$$\begin{aligned} p_{m,n}(x) &= \sum_{k=0}^{\infty} (f(k) - f(k+m+1)) \\ &= (1-x)^{n+1} \sum_{k=0}^{\infty} \frac{(n+1)_k}{k!} x^k - (1-x)^{n+1} \sum_{k=0}^{\infty} \frac{\Gamma(n+m+k+2)}{\Gamma(n+1)\Gamma(m+k+2)} x^{k+m+1} \\ &= 1 - \frac{\Gamma(n+m+2)}{\Gamma(m+2)\Gamma(n+1)} x^{m+1} (1-x)^{n+1} {}_2F_1\left(\begin{matrix} n+m+2, 1 \\ m+2 \end{matrix}; x\right) \\ &= 1 - \frac{\Gamma(n+m+2)}{\Gamma(m+2)\Gamma(n+1)} x^{m+1} {}_2F_1\left(\begin{matrix} -n, m+1 \\ m+2 \end{matrix}; x\right) \\ &= 1 - \frac{\Gamma(n+m+2)}{\Gamma(m+1)\Gamma(n+1)} B_x(m+1, n+1). \end{aligned} \tag{8.3}$$

Here we used Euler's transformation formula [1, (2.2.7)] and (7.3). Note that for $x \in (0, 1)$ and $m, n \in \mathbb{C}$ with $\operatorname{Re} m, \operatorname{Re} n > -1$ the extension of $p_{m,n}(x)$ defined by (8.1) is equal to the extension defined by (8.3). This equality is given by (7.4). Curiously, this equality is also the extension of the identity (1.2).

9 Three-term hypergeometric identities

We can write (1.6) as

$$u_3 = u_1 + u_2, \tag{9.1}$$

where

$$u_1(x) := \sum_{k=0}^m \frac{(n+1)_k}{k!} x^k = {}_2F_1\left(\begin{matrix} -m, n+1 \\ -m \end{matrix}; x\right), \tag{9.2}$$

$$\begin{aligned} u_2(x) &:= x^{m+1} \sum_{k=0}^n \frac{(m+1)_k}{k!} (1-x)^{k-n-1} = x^{m+1} (1-x)^{-n-1} {}_2F_1\left(\begin{matrix} -n, m+1 \\ -n \end{matrix}; 1-x\right) \\ &= \frac{(m+n+1)!}{(m+1)!n!} x^{m+1} (1-x)^{-n-1} {}_2F_1\left(\begin{matrix} m+1, -n \\ m+2 \end{matrix}; x\right), \end{aligned} \tag{9.3}$$

$$u_3(x) := (1-x)^{-n-1} = (1-x)^{-n-1} {}_2F_1\left(\begin{matrix} 0, -m-n-1 \\ -n \end{matrix}; 1-x\right). \tag{9.4}$$

Here the third identity in (9.3) is (7.5). Now u_1 , u_2 and u_3 are three different solutions of the hypergeometric differential equation

$$x(1-x)u''(x) - ((n+2)x + m(1-x))u'(x) + m(n+1)u(x) = 0. \tag{9.5}$$

Indeed, consider Kummer's 24 solutions of the hypergeometric equation

$$z(1-z)u''(z) + (c - (a+b+1)z)u'(z) - abu(z) = 0 \quad (9.6)$$

in [7, §2.9] with $(a, b, c) := (-m, n+1, -m)$. Then u_1, u_2, u_3 above (u_2 up to a constant factor) are equal to (1), (17), (21), respectively, in [7, §2.9]. However, this is for u_1 and u_3 only a formal proof, because there occurs a lower parameter in the hypergeometric function which is a nonpositive integer. For a rigorous argument for u_1 , consider the solution [7, 2.9(1)] of (9.6) first for $(a, b, c) := (-m, n+1, c)$ and then let $c \rightarrow -m$. Also, for u_3 , consider the solution [7, 2.9(21)] of (9.6) first for $c, a := -b - m - n - 1$ with b general, and then let $b \rightarrow n+1$.

For the general theory of solving the hypergeometric differential equation (9.6) see [1, §2.3]. In general, for fixed a, b, c , and on a simply connected domain in \mathbb{C} which avoids the singular points $0, 1$ (and ∞), one can choose two linearly independent solutions and have the general solution as an arbitrary linear combination of these two solutions. For a particular solution the coefficients in the linear combination can be found from (possibly asymptotic) values of the solution at two of the three singular points. In our case of solutions u_1, u_2, u_3 , given by (9.2)–(9.4), the solutions are rational, so they exist as one-valued functions on \mathbb{C} (possibly with a pole in 1). If we would a priori know only that $u_3(x) = Au_1(x) + Bu_2(x)$ then we can compute $A = 1$ by putting $x = 0$ and we can compute $B = 1$ by multiplying both sides of the equality by $(1-x)^{n+1}$, next putting $x = 1$, and then using the Chu-Vandermonde identity [1, Corollary 2.2.3] for the evaluation of ${}_2F_1(m+1, -n; m+2; 1)$.

The case discussed here is the case $m = 0$ in Vidūnas [21, §8] (trivial monodromy group). In this way he obtained (1.6) as the case $m = 0$ of the identity at the end of his section 8.

For $\alpha > 0$ and n, m nonnegative integers we will now prove the following more general three-term identity:

$$\begin{aligned} & (1-z)^{-n-1}(1-z^{-1})^{-\alpha} {}_2F_1\left(\begin{matrix} m+1, -\alpha \\ n+m+2 \end{matrix}; z^{-1}\right) \\ &= \frac{(n+1)_{m+1}}{(n+\alpha+1)_{m+1}} z^{m+1}(1-z)^{-n-1}(1-z^{-1})^{-\alpha} {}_2F_1\left(\begin{matrix} -n, m+1 \\ -n-\alpha \end{matrix}; 1-z\right) \\ & \quad + \frac{(m+1)_{n+1}}{(m+\alpha+1)_{n+1}} {}_2F_1\left(\begin{matrix} -m, n+1 \\ -m-\alpha \end{matrix}; z\right) \quad (z \in \mathbb{C} \setminus [0, 1]). \end{aligned} \quad (9.7)$$

This formula makes good sense on the indicated domain, since ${}_2F_1(a, b; c; z)$, originally defined as a power series for $|z| < 1$, has a unique analytic continuation to $\mathbb{C} \setminus [1, \infty)$. Hence, the ${}_2F_1$ on the left is uniquely defined for $z \notin [0, 1]$. Also, $(1-z^{-1})^\alpha$ is uniquely defined for $z \notin [0, 1]$. The two ${}_2F_1$'s on the right, being polynomials, are defined for all $z \in \mathbb{C}$. If one wishes, one may rewrite $(1-z)^{-n-1}(1-z^{-1})^{-\alpha}$ as $(-1)^{n+1}z^{-n-1}(1-z^{-1})^{-\alpha-n-1}$.

For $\alpha \rightarrow 0$ the identity (9.7) tends to the identity (1.6). In fact, (9.7), which is of the form $u_3 = u_1 + u_2$ (see (9.1)), has the terms u_1, u_2 and u_3 as solutions of the differential equation

$$z(1-z)u''(z) - ((n+2)z + m(1-z) + \alpha)u'(z) + m(n+1)u(z) = 0, \quad (9.8)$$

i.e., the hypergeometric differential equation (9.6) for $(a, b, c) = (-m, n+1, -m-\alpha)$. Indeed, see the solutions [7, 2.9 (18),(1),(14)] of (9.8). This gives u_1 (after substituting (7.6)), u_2 and

u_3 , respectively. For $\alpha \downarrow 0$, (9.8) tends to (9.5), and the solutions u_1, u_2, u_3 of (9.8) tend to the solutions u_1, u_2, u_3 of (9.5).

The case of (9.7) that α is a nonnegative integer is essentially the general case of the identity at the end of section 8 in Vidūnas [21]. Just transform the ${}_2F_1$ on the left of (9.7) by first reversing the order of summation in the hypergeometric series and next applying Pfaff's transformation formula (2.9).

For the proof of (9.7), start with the three-term identity

$$\begin{aligned} {}_2F_1\left(\begin{matrix} m+1, -\alpha \\ n+m+2 \end{matrix}; z\right) &= \frac{\Gamma(n+m+2)\Gamma(n+\alpha+1)}{\Gamma(n+1)\Gamma(n+m+\alpha+2)} z^{-m-1} {}_2F_1\left(\begin{matrix} m+1, -n \\ -n-\alpha \end{matrix}; 1-z^{-1}\right) \\ &+ \frac{\Gamma(n+m+2)\Gamma(-n-\alpha-1)}{\Gamma(m+1)\Gamma(-\alpha)} z^{-n-1}(1-z)^{n+1+\alpha} {}_2F_1\left(\begin{matrix} n+1, -m \\ n+\alpha+2 \end{matrix}; 1-z^{-1}\right) \end{aligned} \quad (z \notin \{0\} \cup [1, \infty)), \quad (9.9)$$

see [7, 2.10(4)] (or [1, (2.3.11)] combined with (2.9)). Note that we don't have to exclude $z \in (-\infty, 0)$ in (9.9) because the two ${}_2F_1$'s on the right are terminating. By (7.6) the last hypergeometric function on the right can be replaced by

$$\frac{(\alpha+1)_m}{(n+\alpha+2)_m} {}_2F_1\left(\begin{matrix} n+1, -m \\ -m-\alpha \end{matrix}; z^{-1}\right).$$

In the identity which thus results from (9.9), first replace z by z^{-1} and next multiply both sides by $(1-z)^{-n-1}(1-z^{-1})^{-\alpha}$. This yields (9.7).

10 A multivariable generalization

A multivariable generalization (1.5) of (1.1) was proved in [17] by generating functions (see the one-variable case of this proof in section 5), while a probabilistic proof, immediately generalizing the one-variable case discussed in Remark 6.1, was indicated in [17] and [22]. We will give in section 12 a different proof of (1.5), which will generalize the proof of (1.1) in section 7 using the beta integral.

Let us reformulate (1.5) in other notation, and let us also give this identity in homogeneous form. Let $s := x_1 + \dots + x_n$. Define

$$\begin{aligned} f_{a_1, \dots, a_n}(x_1, \dots, x_n) &:= x_n^{a_n+1} \sum_{k_1=0}^{a_1} \dots \sum_{k_{n-1}=0}^{a_{n-1}} \frac{(a_n+1)_{k_1+\dots+k_{n-1}}}{k_1! \dots k_{n-1}!} \\ &\times x_1^{k_1} \dots x_{n-1}^{k_{n-1}} s^{a_1+\dots+a_{n-1}-(k_1+\dots+k_{n-1})}. \end{aligned} \quad (10.1)$$

Then

$$(x_1 + \dots + x_n)^{a_1+\dots+a_n+1} = \sum_{\sigma} f_{a_{\sigma(1)}, \dots, a_{\sigma(n)}}(x_{\sigma(1)}, \dots, x_{\sigma(n)}), \quad (10.2)$$

where summation is over all cyclic permutations σ of $1, 2, \dots, n$. For $x_1 + \dots + x_n = 1$ identity (10.2) simplifies to

$$1 = \sum_{\sigma} f_{a_{\sigma(1)}, \dots, a_{\sigma(n)}}(x_{\sigma(1)}, \dots, x_{\sigma(n)}) \quad (10.3)$$

with

$$f_{a_1, \dots, a_n}(x_1, \dots, x_n) = x_n^{a_n+1} \sum_{k_1=0}^{a_1} \dots \sum_{k_{n-1}=0}^{a_{n-1}} \frac{(a_n+1)_{k_1+\dots+k_{n-1}}}{k_1! \dots k_{n-1}!} x_1^{k_1} \dots x_{n-1}^{k_{n-1}}. \quad (10.4)$$

Identity (10.3) is a reformulation of (1.5) and (10.2) is the homogeneous form of (10.3).

Remark 10.1. For $n = 2$ we can write (10.3), (10.4) as

$$1 = f_{m,n}(x, 1-x) + f_{n,m}(1-x, x) \quad \text{with} \quad f_{m,n}(x, 1-x) = (1-x)^{n+1} \sum_{k=0}^m \frac{(n+1)_k}{k!} x^k.$$

So we have (1.1). The case $n = 3$ of (10.3), (10.4) is also noteworthy as a two-variable analogue of (1.1):

$$1 = f_{a,b,c}(x, y, 1-x-y) + f_{b,c,a}(y, 1-x-y, x) + f_{c,a,b}(1-x-y, x, y), \quad (10.5)$$

$$f_{a,b,c}(x, y, 1-x-y) = (1-x-y)^{c+1} \sum_{k=0}^a \sum_{l=0}^b \frac{(c+1)_{k+l}}{k! l!} x^k y^l. \quad (10.6)$$

Identity (10.5) is also given in [17].

If we divide both sides of (10.5) by $(1-x-y)^{c+1}$ then the resulting identity has the form

$$(1-x-y)^{-c-1} = f(x, y) + x^{a+1}g(x, y) + y^{b+1}h(x, y),$$

where $f(x, y)$ is the polynomial consisting of all terms of the power series of $(1-x-y)^{-c-1}$ which have degree $\leq a$ in x and degree $\leq b$ in y , while $g(x, y)$ and $h(x, y)$ are power series in x and y . There does not seem to be an a priori symmetry argument which settles (10.5) from this observation. For instance, if we try to imitate the proof for $n = 2$ in section 2 then we have to consider the homogeneous version of (10.5) given by (10.2) for $n = 3$:

$$(x+y+z)^{a+b+c+1} = f_{a,b,c}(x, y, z) + f_{b,c,a}(y, z, x) + f_{c,a,b}(z, x, y).$$

The problem is where to put on the right the terms $\gamma_{k,l,m} x^k y^l z^m$ ($k+l+m = a+b+c+1$) in the expansion of $(x+y+z)^{a+b+c+1}$. Certainly, we can uniquely put all terms $\gamma_{k,l,m} x^k y^l z^m$ with $k \leq a$, $l \leq b$ in $f_{a,b,c}(x, y, z)$, all terms with $l \leq b$, $m \leq c$ in $f_{b,c,a}(y, z, x)$, and all terms with $m \leq c$, $k \leq a$ in $f_{c,a,b}(z, x, y)$, but there is no clear rule where to put a term in which only one of the three inequalities $k \leq a$, $l \leq b$, $m \leq c$ holds.

Remark 10.2. Note that we can formally express the right-hand side of (10.6) in terms of Appell's hypergeometric function F_2 (see [7, §5.7.1]):

$$f_{a,b,c}(x, y, 1-x-y) = (1-x-y)^{c+1} F_2(c+1, -a, -b, -a, -b, x, y).$$

However, due to the nonpositive integer bottom parameters we cannot transform this F_2 function by [7, 5.11(8)] similarly as we transformed the ${}_2F_1$ function in Remark 2.1.

Similarly to the case $n = 3$, the multisum on the right-hand side of (10.4) can be formally written as a *Lauricella hypergeometric function* F_A (see [2, Ch. VII] or [13, (8.6.1)]):

$$f_{a_1, \dots, a_n}(x_1, \dots, x_n) = x_n^{a_n+1} F_A^{(n-1)}(a_n + 1, -a_1, \dots, -a_{n-1}, -a_1, \dots, -a_{n-1}; x_1, \dots, x_{n-1}) \\ (x_1 + \dots + x_n = 1). \quad (10.7)$$

Here the $F_A^{(n-1)}$ has to be interpreted as

$$\lim_{(b_1, \dots, b_{n-1}) \rightarrow (-a_1, \dots, -a_{n-1})} F_A^{(n-1)}(a_n + 1, -a_1, \dots, -a_{n-1}, b_1, \dots, b_{n-1}; x_1, \dots, x_{n-1}). \quad (10.8)$$

11 A PDE associated with the multivariable identity

From the expression in (10.7) of $f_{a_1, \dots, a_n}(x_1, \dots, x_{n-1}, 1 - x_1 - \dots - x_{n-1})$ in terms of a Lauricella hypergeometric function, we will derive a PDE for f_{a_1, \dots, a_n} . Consider first the system of PDE's for the $F_A^{(n-1)}$ in (10.8), as given in [2, Ch. VII, §XXXIX] (for $n = 3$ we have Appell's hypergeometric function F_2 and then the system of PDE's is also given in [7, 5.9(10)]). After taking the limit for $(b_1, \dots, b_{n-1}) \rightarrow (-a_1, \dots, -a_{n-1})$ we obtain that

$$u(x_1, \dots, x_{n-1}) := F_A^{(n-1)}(a_n + 1, -a_1, \dots, -a_{n-1}, -a_1, \dots, -a_{n-1}; x_1, \dots, x_{n-1}) \quad (11.1)$$

satisfies the system of PDE's

$$x_i(1 - x_i)\partial_i^2 u - x_i \sum_{j \neq i} x_j \partial_j \partial_i u - (a_i + (a_n + 2)x_i)\partial_i u + a_i \sum_j x_j \partial_j u + (a_n + 1)a_i u = 0 \\ (i = 1, \dots, n - 1).$$

Here ∂_i denotes $\partial/\partial x_i$. The sum of the $n - 1$ PDE's equals

$$\sum_i x_i(1 - x_i)\partial_i^2 u - \sum_{i \neq j} x_i x_j \partial_i \partial_j u + (a_1 + \dots + a_{n-1} - a_n - 2) \sum_i x_i \partial_i u - \sum_i a_i \partial_i u \\ + (a_n + 1)(a_1 + \dots + a_{n-1})u = 0. \quad (11.2)$$

Proposition 11.1. *The function (11.1) is the unique solution, up to a constant factor, of (11.2) which has the form*

$$u(x_1, \dots, x_{n-1}) = \sum_{k_1=0}^{a_1} \dots \sum_{k_{n-1}=0}^{a_{n-1}} \gamma_{k_1, \dots, k_{n-1}} x_1^{k_1} \dots x_{n-1}^{k_{n-1}}. \quad (11.3)$$

Proof Computation of the left-hand side of (11.2) with $u := x_1^{k_1} \dots x_{n-1}^{k_{n-1}}$ yields

$$((a_1 - k_1) + \dots + (a_{n-1} - k_{n-1}))(a_n + 1 + k_1 + \dots + k_{n-1})x_1^{k_1} \dots x_{n-1}^{k_{n-1}} \\ + \left(\sum_{i=1}^{n-1} k_i(k_i - a_i - 1)x_i^{-1} \right) x_1^{k_1} \dots x_{n-1}^{k_{n-1}}.$$

It follows that u of the form (11.3) satisfies (11.2) iff

$$\begin{aligned} & ((a_1 - k_1) + \cdots + (a_{n-1} - k_{n-1}))(a_n + 1 + k_1 + \cdots + k_{n-1})\gamma_{k_1, \dots, k_{n-1}} \\ & + \sum_{i=1}^{n-1} (k_i + 1)(k_i - a_i)\gamma_{k_1, \dots, k_i+1, \dots, k_{n-1}} = 0. \end{aligned} \quad (11.4)$$

Give some value to $\gamma_{a_1, \dots, a_{n-1}}$. Then we see from (11.4) by downward induction with respect to $k_1 + \cdots + k_{n-1}$ that all coefficients $\gamma_{k_1, \dots, k_{n-1}}$ with $0 \leq k_i \leq a_i$ ($i = 1, \dots, n-1$) are uniquely determined by this initial value.

In passing we see that (11.4) is satisfied by

$$\gamma_{k_1, \dots, k_{n-1}} := \frac{(a_n + 1)_{k_1 + \dots + k_{n-1}}}{k_1! \cdots k_{n-1}!}.$$

Thus we have also proved from scratch that u given by (11.1) satisfies (11.2). \square

By some computation, we see that

$$\begin{aligned} v(x_1, \dots, x_{n-1}) & := (1 - x_1 - \cdots - x_{n-1})^{a_n+1} u(x_1, \dots, x_{n-1}) \\ & = f_{a_1, \dots, a_n}(x_1, \dots, x_{n-1}, 1 - x_1 - \cdots - x_{n-1}) \end{aligned}$$

satisfies the PDE

$$\sum_{i=1}^{n-1} x_i(1 - x_i)\partial_i^2 v - 2 \sum_{i < j} x_i x_j \partial_i \partial_j v + \sum_{i=1}^{n-1} \left((a_1 + \cdots + a_n)x_i - a_i \right) \partial_i v = 0. \quad (11.5)$$

Clearly, the function $v := 1$ satisfies (11.5). Furthermore, by straightforward computations we see: If v satisfies (11.5) then the function $(x_1, \dots, x_{n-1}) \mapsto v(1 - x_1 - \cdots - x_{n-1}, x_2, \dots, x_{n-1})$ satisfies (11.5) with a_1 and a_n interchanged. Thus we have proved:

Theorem 11.2. *For all permutations σ of $1, 2, \dots, n$ the functions*

$$(x_1, \dots, x_{n-1}) \mapsto f_{a_{\sigma(1)}, \dots, a_{\sigma(n)}}(x_{\sigma(1)}, \dots, x_{\sigma(n)}) \quad (x_1 + \cdots + x_n = 1)$$

are solutions of (11.5). Up to a constant factor they are the unique solutions of (11.5) of the form

$$v(x_1, \dots, x_{n-1}) = x_{\sigma(n)}^{a_{\sigma(n)}+1} \sum_{k_1=0}^{a_{\sigma(1)}} \cdots \sum_{k_{n-1}=0}^{a_{\sigma(n-1)}} \gamma_{k_1, \dots, k_{n-1}} x_{\sigma(1)}^{k_1} \cdots x_{\sigma(n-1)}^{k_{n-1}} \quad (x_1 + \cdots + x_n = 1). \quad \square$$

Now consider a solution $v(x_1, \dots, x_{n-1})$ of (11.5), let x_n be a variable independent of x_1, \dots, x_{n-1} , and let ϕ be an arbitrary function of that new variable. Then trivially (11.5) holds with v replaced by $\phi(x_n)v(x_1, \dots, x_{n-1})$. Now pass in this PDE to new variables y_1, \dots, y_n by

$$x_1 = \frac{y_1}{y_1 + \cdots + y_n}, \quad \dots, \quad x_{n-1} = \frac{y_{n-1}}{y_1 + \cdots + y_n}, \quad x_n = y_1 + \cdots + y_n,$$

or equivalently,

$$y_1 = x_1 x_n, \dots, y_{n-1} = x_{n-1} x_n, \quad y_n = (1 - x_1 - \dots - x_{n-1}) x_n.$$

Then we obtain that the function $w(y_1, \dots, y_n) := \phi(y_1 + \dots + y_n) v\left(\frac{y_1}{y_1 + \dots + y_n}, \dots, \frac{y_{n-1}}{y_1 + \dots + y_n}\right)$ satisfies the PDE

$$\sum_{i=1}^n y_i (y_1 + \dots + y_n - y_i) \partial_i^2 w - 2 \sum_{i < j} y_i y_j \partial_i \partial_j w + \sum_{i=1}^n \left((a_1 + \dots + a_n) y_i - a_i (y_1 + \dots + y_n) \right) \partial_i w = 0, \quad (11.6)$$

where ∂_i denotes $\partial/\partial y_i$. Thus by (10.1), (10.4) and Theorem 11.2 we have proved in particular:

Theorem 11.3. *The function $w(y_1, \dots, y_n) := f_{a_1, \dots, a_n}(y_1, \dots, y_n)$, defined by (10.1), satisfies (11.6). Similarly, the functions $w(y_1, \dots, y_n) := f_{a_{\sigma(1)}, \dots, a_{\sigma(n)}}(y_{\sigma(1)}, \dots, y_{\sigma(n)})$ satisfy (11.6), where σ is a permutation of $1, \dots, n$. Also, the function $w(y_1, \dots, y_n) := (y_1 + \dots + y_n)^{a_1 + \dots + a_n + 1}$ satisfies (11.6).*

12 Splitting up Dirichlet's multivariable beta integral

Just as (1.6) can be obtained by splitting a beta integral into two parts and evaluating the resulting incomplete beta integrals, we can prove and interpret (10.3) by splitting Dirichlet's $(n-1)$ -dimensional beta integral with nonnegative integer exponents into n parts. For convenience, we will work here with an n -dimensional beta integral.

Let Δ_n be the simplex in \mathbb{R}^n with vertices 0 and the standard basis vectors e_1, \dots, e_n . Let a_1, \dots, a_n, b be complex numbers with real part > -1 . Then Dirichlet's integral is as follows.

$$I_{a_1, \dots, a_{n+1}} := \int_{\Delta_n} t_1^{a_1} \dots t_n^{a_n} (1 - t_1 - \dots - t_n)^{a_{n+1}} dt_1 \dots dt_n = \frac{\Gamma(a_1 + 1) \dots \Gamma(a_{n+1} + 1)}{\Gamma(a_1 + \dots + a_{n+1} + n + 1)}, \quad (12.1)$$

see [1, Theorem 1.8.6] or [6, Exercise 7.2.6] for a straightforward proof, and [8] for its history. Note that $I_{a_1, \dots, a_{n+1}}$ is symmetric in a_1, \dots, a_{n+1} .

Now take $x = (x_1, \dots, x_n)$ within Δ_n and let $\Delta_n^{(i)}(x)$ ($i = 1, \dots, n+1$) denote the simplex in \mathbb{R}^n which has a vertex x and n further vertices taken from $0, e_1, \dots, e_n$ where e_i is deleted if $i = 1, \dots, n$ and 0 is deleted if $i = n+1$. Require that a_1, \dots, a_{n+1} are nonnegative integers. Define

$$I_{a_1, \dots, a_{n+1}}^{(i)}(x) := \int_{\Delta_n^{(i)}(x)} t_1^{a_1} \dots t_n^{a_n} (1 - t_1 - \dots - t_n)^{a_{n+1}} dt_1 \dots dt_n. \quad (12.2)$$

For any $(y_1, \dots, y_n) \in \mathbb{R}^n$ put $y_{n+1} := 1 - y_1 - \dots - y_n$. Then, for any permutation σ of $1, 2, \dots, n+1$ (i.e., $\sigma \in S_{n+1}$), the map $(y_1, \dots, y_n) \mapsto (y_{\sigma(1)}, \dots, y_{\sigma(n)})$ is a diffeomorphism of Δ_n with Jacobian having absolute value 1. Thus we have the identity

$$I_{a_1, \dots, a_{n+1}}^{(i)}(x_1, \dots, x_n) = I_{a_{\sigma(1)}, \dots, a_{\sigma(n+1)}}^{(\sigma^{-1}(i))}(x_{\sigma(1)}, \dots, x_{\sigma(n)}) \quad (\sigma \in S_{n+1}). \quad (12.3)$$

Define

$$f_{a_1, \dots, a_{n+1}}(x) := (1 - x_1 - \dots - x_n)^{a_{n+1} + 1} \sum_{k_1=0}^{a_1} \dots \sum_{k_n=0}^{a_n} \frac{(a_{n+1} + 1)_{k_1 + \dots + k_n}}{k_1! \dots k_n!} x_1^{k_1} \dots x_n^{k_n}, \quad (12.4)$$

i.e., (10.1) with n replaced by $n + 1$ and with $x_{n+1} := 1 - x_1 - \dots - x_n$ omitted in the argument. We have the symmetry

$$f_{a_1, \dots, a_{n+1}}(x_1, \dots, x_n) = f_{a_{\sigma(1)}, \dots, a_{\sigma(n)}, a_{n+1}}(x_{\sigma(1)}, \dots, x_{\sigma(n)}) \quad (\sigma \in S_n). \quad (12.5)$$

Proposition 12.1. *For nonnegative integers a_1, \dots, a_{n+1} and for x within Δ_n we have:*

$$\frac{I_{a_1, \dots, a_{n+1}}^{(n)}(x)}{I_{a_1, \dots, a_{n+1}}} = f_{a_{n+1}, a_1, \dots, a_n}(1 - x_1 - \dots - x_n, x_1, \dots, x_{n-1}). \quad (12.6)$$

Proof For convenience put $b := a_{n+1}$ and $x' := (x_1, \dots, x_{n-1})$. Then

$$\begin{aligned} I_{a_1, \dots, a_n, b}^{(n)}(x) &= \int_0^{x_n} t_n^{a_n} \left(\int_{(t_n/x_n)x' + (1-t_n/x_n)\Delta_{n-1}} t_1^{a_1} \dots t_{n-1}^{a_{n-1}} (1 - t_1 - \dots - t_n)^b dt_1 \dots dt_{n-1} \right) dt_n \\ &= x_n^{a_n+1} \int_0^1 s^{a_n} \left(\int_{sx' + (1-s)\Delta_{n-1}} t_1^{a_1} \dots t_{n-1}^{a_{n-1}} (1 - t_1 - \dots - t_{n-1} - sx_n)^b dt_1 \dots dt_{n-1} \right) ds \\ &= x_n^{a_n+1} \int_0^1 s^{a_n} (1-s)^{n-1} \left(\int_{\Delta_{n-1}} (sx_1 + (1-s)s_1)^{a_1} \dots (sx_{n-1} + (1-s)s_{n-1})^{a_{n-1}} \right. \\ &\quad \left. \times (s(1-x_1 - \dots - x_n) + (1-s)(1-s_1 - \dots - s_{n-1}))^b ds_1 \dots ds_{n-1} \right) ds \\ &= x_n^{a_n+1} \sum_{k_1=0}^{a_1} \dots \sum_{k_{n-1}=0}^{a_{n-1}} \sum_{l=0}^b \binom{a_1}{k_1} \dots \binom{a_{n-1}}{k_{n-1}} \binom{b}{l} x_1^{k_1} \dots x_{n-1}^{k_{n-1}} (1-x_1 - \dots - x_n)^l \\ &\quad \times \int_0^1 s^{a_n+k_1+\dots+k_{n-1}+l} (1-s)^{a_1+\dots+a_{n-1}+b+n-1-k_1-\dots-k_{n-1}-l} ds \\ &\quad \times \int_{\Delta_{n-1}} s_1^{a_1-k_1} \dots s_{n-1}^{a_{n-1}-k_{n-1}} (1-s_1 - \dots - s_{n-1})^{b-l} ds_1 \dots ds_{n-1} \\ &= x_n^{a_n+1} \sum_{k_1=0}^{a_1} \dots \sum_{k_{n-1}=0}^{a_{n-1}} \sum_{l=0}^b \binom{a_1}{k_1} \dots \binom{a_{n-1}}{k_{n-1}} \binom{b}{l} x_1^{k_1} \dots x_{n-1}^{k_{n-1}} (1-x_1 - \dots - x_n)^l \\ &\quad \times \frac{\Gamma(a_n+k_1+\dots+k_{n-1}+l+1)\Gamma(a_1+\dots+a_{n-1}+b+n-k_1-\dots-k_{n-1}-l)}{\Gamma(a_1+\dots+a_n+b+n+1)} \\ &\quad \times \frac{\Gamma(a_1-k_1+1)\dots\Gamma(a_{n-1}-k_{n-1}+1)\Gamma(b-l+1)}{\Gamma(a_1+\dots+a_{n-1}+b+n-k_1-\dots-k_{n-1}-l)} \\ &= \frac{a_1! \dots a_n! b!}{(a_1+\dots+a_n+b+n)!} \\ &\quad \times x_n^{a_n+1} \sum_{k_1=0}^{a_1} \dots \sum_{k_{n-1}=0}^{a_{n-1}} \sum_{l=0}^b \frac{(a_n+1)_{k_1+\dots+k_{n-1}+l}}{k_1! \dots k_{n-1}! l!} x_1^{k_1} \dots x_{n-1}^{k_{n-1}} (1-x_1 - \dots - x_n)^l \\ &= I_{a_1, \dots, a_n, b} f_{b, a_1, \dots, a_{n-1}, a_n}(1-x_1 - \dots - x_n, x_1, \dots, x_{n-1}). \quad \square \end{aligned}$$

Theorem 12.2. Let a_1, \dots, a_{n+1} and x as before. Let $i \in \{1, 2, \dots, n+1\}$ and let σ be the cyclic permutation of $1, \dots, n+1$ which sends n to i . Then

$$\frac{I_{a_1, \dots, a_{n+1}}^{(i)}(x)}{I_{a_1, \dots, a_{n+1}}} = f_{a_{\sigma(n+1)}, a_{\sigma(1)}, \dots, a_{\sigma(n)}}(x_{\sigma(n+1)}, x_{\sigma(1)}, \dots, x_{\sigma(n)}). \quad (12.7)$$

Proof By (12.3) we have $\frac{I_{a_1, \dots, a_{n+1}}^{(i)}(x)}{I_{a_1, \dots, a_{n+1}}} = \frac{I_{a_{\sigma(1)}, \dots, a_{\sigma(n+1)}}^{(n)}(x_{\sigma(1)}, \dots, x_{\sigma(n)})}{I_{a_{\sigma(1)}, \dots, a_{\sigma(n+1)}}}$. Now apply (12.6). \square

We have the obvious identity

$$1 = \sum_{i=1}^{n+1} \frac{I_{a_1, \dots, a_{n+1}}^{(i)}(x)}{I_{a_1, \dots, a_{n+1}}} \quad (x \in \Delta_n, a_1, \dots, a_{n+1} \in \mathbb{C}, \operatorname{Re} a_1, \dots, \operatorname{Re} a_{n+1} > -1). \quad (12.8)$$

By Theorem 12.2 this is for nonnegative integers a_1, \dots, a_{n+1} equivalent with (10.3) (with n replaced by $n+1$ and with the functions $f_{a_1, \dots, a_{n+1}}$ defined by (10.4)). In the general case of (12.8) we get an extension of (10.3) for non-integer a_1, \dots, a_{n+1} , just as we discussed in the one-variable case in section 8. The uniqueness of the extension if the terms satisfy estimates as in Carlson's theorem, as discussed there, also holds here.

Remark 12.3. It is an interesting question (but for us a nontrivial open problem) to find an elegant looking evaluation of (12.2) which is valid for all complex a_1, \dots, a_{n+1} with real part > -1 , and which would generalize the evaluation (7.3) of the incomplete beta function. This would also give an n -variable generalization of (7.5), i.e., of a limit case of Pfaff's identity (7.6).
