Abstract

A new small *Phrynobatrachus* species from a gallery forest in north-western Guinea is described. *Phrynobatrachus pinto* **sp. nov.** exhibits a combination of unique morphological characters and a distinctive color pattern, including: compact, oval body, short snout, warty dorsum and eyelid (although no eyelid cornicle is present), three pairs of large symmetric black spots on throat and breast, black spots on belly, more than one black bar on thighs and lower leg, finger and toe tips not expanded, and rudimentary web on foot. Furthermore, analysis of mitochondrial DNA from 16S rRNA reveals that this new species differs from other West African species of the genus by a minimum distance of 7%. Genetically the new species is closest to *Phrynobatrachus fraterculus*, *P. cornutus*, and *P. gutturosus*.

Key words: *Phrynobatrachus pinto* **sp. nov.**, conservation, gallery forest, Upper Guinea Forest zone

Introduction

The genus *Phrynobatrachus* Günther, 1862, family Phrynobatrachidae Laurent, 1941, currently comprises 76 species and is endemic to savannas and forests in sub-Saharan Africa (Poynton 1999; IUCN *et al.* 2004; Frost 2007). Seventeen valid species are recognized to occur in West Africa west of the Dahomey Gap, the majority living in forest habitats (Schjøtz 1964; Perret 1988; Rödel & Ernst 2002b; Rödel *et al.* 2005a). Currently 13 *Phrynobatrachus* species are known to occur in Guinea (Guibé & Lamotte 1963; Rödel & Bangoura 2004; Rödel *et al.* 2004; Greenbaum & Carr 2005). During a recent survey in north-western Guinea (Hillers *et al.* 2006) we detected a small forest *Phrynobatrachus* that was not assignable to a described species. Subsequent morphological and genetic analyses revealed that it represents an unknown species that we describe herein.

Material and methods

Measurements were taken by one person (MOR) with a dial caliper (± 0.1 mm) or with an ocular micrometer in a dissecting microscope (± 0.1 mm, Zeiss Stemi SV 6). Additionally, we recorded the structure of the dorsal and ventral skin, and the color pattern. For comparative material investigated see Rödel and Ernst (2002b) and Appendix 1. Collection abbreviations: MCZ = Museum of Comparative Zoology at Harvard University, ZMB = Zoologisches Museum Berlin (Museum of Natural History, Humboldt University Berlin). The geographic position of the type locality was collected with a handheld GPS receiver (Garmin 12XL).

We analyzed approximately 560 base pairs (bp) of mitochondrial 16S ribosomal RNA from all available West African *Phrynobatrachus* species (Table 1, Appendix 1). DNA was extracted using either QIAamp or DNeasy tissue extraction kits (Qiagen) or High Pure PCR Template Preparation kits (Roche). We used the primers 16SA-L and 16SB-H of Palumbi *et al.* (1991) to amplify the 16S rRNA gene. Standard PCR protocols were used and PCR products were purified using QIAquick purification kits (Qiagen) or High Pure PCR Product Purification kits (Roche). Purified templates were directly sequenced using an automated sequencer (ABI 377 or ABI 3100). Sequences were validated using SEQUENCE NAVIGATOR (Applied Biosystems), aligned using the Clustal option in MEGA 3.1 and refined by eye. Uncorrected pairwise sequence divergence was calculated using PAUP* (version 4beta10).

TABLE 1. Genetic distances (uncorrected p) in the mitochondrial 16S ribosomal DNA of *Phrynobatrachus* species, compared to *P. pinto* **sp. nov.** (GB: EU718711). * *P. calcaratus* from various West African countries were included as this name seems to comprise several cryptic species. For locality data of the tissue vouchers see Appendix 1.

Results

Phrynobatrachus pinto **sp. nov.**

Figs 1–2

Holotype. ZMB 70689 (GB: EU718711, field and tissue #: MOR BO167), gallery forest, 11°06.377' N, 13°57.595' W, Kewewol / Boulléré, Boké Préfecture / Sangaredi sub-Préfecture, Guinea, 5 May 2005, collected by A. Hillers, N.S. Loua and M.A. Bangoura.

Diagnosis. The genetic results indicate that the new species belongs to the genus *Phrynobatrachus*. Morphologically this is visible by the body shape; presence of a tarsal tubercle; presence of rudimentary webbing, presence of dorsal warts in the neck region; lack of black spot in the tympanal region; lack of fine medial dorsal depression; lack of parallel dorsal ridges; neither finger nor toe tips heart shaped nor expanded to discs.

Small, compact *Phrynobatrachus*, characterized by combination of warty back; warty eyelids (eyelid cornicle absent); large dark spots on white throat, breast and belly; rudimentary webbing.

FIGURE 1. Dorsolateral and ventral view of *Phrynobatrachus pinto* sp. nov. (ZMB 70689, holotype).

Description (measures in mm). Typical, semi-adult *Phrynobatrachus* with oval, compact body shape; snout-vent-length: 10.19; short, rounded snout; canthus rostralis indistinct; loreal region straight to slightly concave; head-width directly behind the eyes: 3.75; eye-diameter: 0.96; distance eye-nostril: 0.96; distance nostril-snout tip: 0.39; nostril closer to snout than to eye; tympanum indistinct, much smaller than diameter of

eye; femur: 5.62, slightly shorter than tibio-fibulare: 5.89; foot including longest toe: 8.41 (right foot missing); hand with large and oval palmar and thenar tubercle; fingers with small roundish subarticular tubercles, no additional tubercles on hands; relative finger length: $4=1=2<3$; palmar webbing absent; tarsal tubercle present but not conspicuous; larger internal and smaller external metatarsal tubercle; relative toe length: $1<2<5<3<4$; only rudiments of webbing on toe bases; neither toe nor finger tips expanded to discs.

Dorsal skin grainy; back and eyelids with warts; larger pointed wart in posterior corner of eyelid, resembles eyelid cornicle of various other small *Phrynobatrachus* species but is less distinct; small whitish warts between posterior corner of the eye and forearm bases; two symmetrical pairs of dorsal warts especially pronounced: smaller roundish warts on neck and comma shaped warts directly posterior to symmetrical pairs; various other, smaller warts on back and hind legs; skin of throat corrugated; ventral skin otherwise smooth.

Overall coloration of the dorsum clear brown; indistinct darker bars on upper lip; warts on back rimmed almost black: unpaired roundish spot between posterior part of eyelids, paired roundish and comma shaped pairs of black bordered spots posterior to it; further dark bordered spots irregularly spread on posterior part of back; large pair of symmetrical black bordered spots between base of hind legs; flanks with dark blotch originating dorsal to base of forelimbs, extending ventrally to the middle of body; blackish spots in groin area just extending to back; lower arm with one black bar; thighs and lower leg with three black bars each; vent bordered black; outer parts of thighs with clear longitudinal band, bordered black posterior ventrally; basic color of throat white; mandible with eight black spots; throat and breast with three symmetric pairs of large blackish spots, increasing in size posteriorly; belly with eight irregularly spread blackish spots; ventral parts of thighs white with blackish spots, posterior part near vent speckled brownish; ventral parts of lower legs whitish, border of dorsal black bars visible; color in preservation possibly a bit faded, otherwise not different to life.

FIGURE 2. Eyelids of a) *Phrynobatrachus pinto* sp. nov. (ZMB 70689, holotype), b) *P. cornutus* (ZMB 70745) and c) *P. villiersi* (ZMB 70746).

Genetics. *Phrynobatrachus pinto* differed between 7-16% in the 560 investigated base pairs of the 16S rRNA gene from 17 West African and Central African species of the genus *Phrynobatrachus* (Table 1).

Natural History. The holotype was collected in a gallery forest in the Boulléré / Sangaredi area. This gallery forest was situated in a small depression surrounded by savanna habitat. In the area where *P. pinto* was found, the forest was approximately 150 m wide. The edges were dominated by shrubs, while there were a small number of larger trees in the central section, with a more important canopy and open shrub stratum. *P. pinto* was found in the leaf litter of this central area, close to the river. The soil was partly sandy with some stones and mainly covered with leaf litter. With the exception of the gallery forests, the general landscape in the Boulléré / Sangaradi area was dominated by savanna habitats on bauxite outcrops. These habitats were highly disturbed due to a number of settlements and agricultural encroachment (Wright *et al.* 2006). The

recorded anuran fauna was mainly dominated by savanna species but also included farmbush species, e.g. *Phrynobatrachus tokba*, and one forest species, *Astylosternus* cf. *occidentalis* (Hillers *et al.* 2006). No other data on the biology and ecology of *P. pinto* are known. As all other morphologically similar *Phrynobatrachus* species are forest dwelling, we believe *P. pinto* is forest dependant as well. Further data on habitat, flora and fauna of the region are provided by Wright *et al.* (2006).

Distribution. *Phrynobatrachus pinto* is only known from the type locality.

Etymology. The species is named in honor of Mr. Sidy Mohamed Diawara, known as Pinto. With his outstanding personality and effort he contributed greatly to successful field research and nature conservation in Guinea. He was team-member of the NGO “Guinée Ecologie” and was involved in several Rapid Assessment Programs (RAP). The RAP in the Boké region was his last before he died in September 2006.

Discussion

Apart from *Phrynobatrachus brongersmai* Parker, 1936, *P. taiensis* Perret, 1988, and an undescribed species from mountainous south-eastern Guinea (Rödel & Bangoura 2004), we could compare the 16S rRNA of the new species to all other *Phrynobatrachus* known to occur in West Africa. *P. brongersmai* differs from the new species by having small but distinct discs on toes that are half webbed, a presumably larger size (SVL: 21–27 mm), four dorsal warts that form an X-shaped pattern and brown stippling on the gular and pectoral regions (Parker 1936); whereas *P. pinto* has no discs, almost no webbing, differently shaped dorsal warts and distinct black blotches on the throat. The *Phrynobatrachus* sp. from the Simandou Range has a differently colored venter (less distinctly delimited or smaller spots), a more distinctly black lateral band, a more elongated body and a more pointed snout than *P. pinto*.

Morphologically *P. pinto* is most similar to a variety of other small West African *Phrynobatrachus* species, i.e. *P. annulatus* Perret, 1966, *P. calcaratus* (Peters, 1863), *P. cornutus* (Boulenger, 1906), *P. ghanensis* Schiøtz, 1964, *P. guineensis* Guibé and Lamotte, 1961, *P. phyllophilus* Rödel and Ernst, 2002, *P. taiensis* Perret, 1988 and *P. villiersi* Guibé, 1959. Within this group the new species is genetically closest to *P. cornutus* (8% difference) and *P. villiersi* (9% difference). These two differ by the presence of an eyelid cornicle. *P. villiersi* has a venter with a blackish, reticulated pattern on clear blue ground. *P. cornutus* usually has an almost uniform dark (males) or white throat with black bars on the mandible (females, for an exception see MHNG 1031.14 in Fig. 4, Perret 1988). From *P. calcaratus*, *P. annulatus*, and *P. taiensis* the new species likewise differs by the lack of an eyelid cornicle and a differing ventral coloration (see Perret 1988). *P. pinto* differs from *P. guineensis* and *P. phyllophilus* by its almost absent webbing and the lack of expanded toe and finger tips. These are yellow in *P. guineensis*, but do not differ in color from the rest of the finger or toe in *P. pinto*. *P. guineensis* has similar warts on the eyelids and on the back as *P. pinto*, but always possess bright yellow markings in the groin area. This region is black in the new species. *P. phyllophilus* has almost always only one dark bar on thighs and lower leg, *P. pinto* has three. *P. ghanensis* is similar to *P. pinto* in body shape, warty eyelids and ventral coloration but differs genetically by almost 15% and morphologically by better developed webbing and very well developed discs on toes. Small differences in color pattern are black bars on the upper lip that are very distinct in *P. ghanensis* (Fig. 4 in Asseman *et al.* 2006). The black ventral spots of the latter species often have a clearer center or are less distinctly delimited (Schiøtz 1964; Perret 1988) than in *P. pinto*.

Numerous morphological characteristics differentiate *P. pinto* from other West African *Phrynobatrachus* species. *Phrynobatrachus alleni* Parker, 1936, *P. batesii* (Boulenger, 1906), *P. liberiensis* Barbour and Loveridge, 1927, *P. natalensis* (Smith, 1849), and *P. plicatus* (Günther, 1859 “1858”) are all much larger than *P. pinto*, differ in body shape, have uniform colored white or yellow (adult *P. alleni* males) bellies and have extensive webbing. In *P. alleni* and *P. plicatus* the dorsal warts are short (*P. alleni*) or elongate (*P. plicatus*) X-shapes. *P. accraensis* (Ahl, 1925 “1923”) and *P. francisci* Boulenger, 1912 have white venters and distinct

webbing. *P. gutturosus* (Chabanaud, 1921) lacks webbing, but has a uniform white belly and a much more elongated body shape. *P. fraterculus* (Chabanaud, 1921), which was most similar to *P. pinto* genetically (7% difference), possess a very distinctly marked black lateral band, small blackish spots on the belly, has a more elongated body shape, completely smooth skin and presumably is larger (females known to reach 26 mm; see Fig. 2c in Rödel & Bangoura 2004).

From our knowledge with other, similar shaped *Phrynobatrachus* species, we believe that adults of *P. pinto* will not be much larger than 20 mm body length (for measurements of West African *Phrynobatrachus* see Guibé & Lamotte 1963; Perret 1988; Rödel 2000; Rödel & Ernst 2002b). *P. tokba* (Chabanaud, 1921) is also a very small species but differs from the new one by a differently shaped, more elongated body and converging dorsal warts (see Fig. 1A & B in Rödel & Ernst 2002a and Fig. 3 in Rödel *et al.* 2005a; second pair of neck warts comma shaped in *P. pinto*), as well as a uniform clear colored breast and belly (Rödel *et al.* 2005a).

The genus *Phrynobatrachus* is a very diverse and taxonomically difficult African frog genus (Poynton 1999), with very variable species (Stewart 1974; Rödel 2000). A description of a new species at first did not seem to be advisable because only a single sub-adult specimen was available for analysis. However, even with extensive examination of thousands of living and preserved specimens from almost all West African *Phrynobatrachus* species, we (AH, MOR) failed to assign this frog to a described species. As we found both morphological and genetic evidence for the specific distinctiveness of our new taxon, we regarded this description as justified. Giving the presumably restricted distribution of the new species in an area of intense human pressure, naming was a necessity also concerning conservation. Currently *P. pinto* has to be classified as Data Deficient. However, future work in the area may reveal that the conservation status of the new species, potentially having a very restricted distribution in a habitat type that is under huge human pressure, may be Critically Endangered. This discovery is a further hint that even very small and / or isolated West African forests still may hold herpetological novelties (Ernst *et al.* 2008) and facing the current rates of deforestation (FAO 2006) should be urgently assessed for their fauna.

Acknowledgements

We are indebted to Conservation International, Washington D.C., in general and L.E. Alonso and J. McCullough in particular for the invitation to participate in this survey of the Rapid Assessment Program. M.S. Diallo, director of the NGO Guinée Ecologie, and his team were responsible for logistics. We thank them as well as the other RAP members, especially M.A. Bangoura and N.S. Loua, for their invaluable help during fieldwork and for their companionship. Mrs. C.S. Kourouma at the "Ministère de l'Agriculture des Eaux et Forêts", Republic of Guinea, issued the collecting and export permissions (Code 100, Nr. 000741-742). Analyzing and publication of the data was part of the DFG-project VE 183/4-1 & RO 306/1-2. J. Kosuch contributed sequences for *Phrynobatrachus gutturosus* and *P. natalensis*. BZ is supported by the Department of Organismic and Evolutionary Biology and Museum of Comparative Zoology, Harvard University. This support is gratefully acknowledged!
