A CLOSER LOOK AT DECLARATIVE INTERPRETATIONS*

KRZYSZTOF R. APT, MAURIZIO GABBRIELLI, AND DINO PEDRESCHI

Three semantics have been proposed as the most promising candidates for a declarative interpretation for logic programs and pure Prolog programs: the least Herbrand model, the least term model, i.e., the $^\mathcal{E}$-semantics, and the $^\mathcal{S}$-semantics. Previous results show that a strictly increasing information ordering between these semantics exists for the class of all programs. In particular, the $^\mathcal{S}$-semantics allows us to model the computed answer substitutions, which is not the case for the other two.

We study here the relationship between these three semantics for specific classes of programs. We show that for a large class of programs (which is Turing complete), these three semantics are isomorphic. As a consequence, given a query, we can extract from the least Herbrand model of a program in this class all computed answer substitutions. However, for specific programs the least Herbrand model is tedious to construct and reason about because it contains "ill-typed" facts. Therefore, we propose a fourth semantics that associates with a "correctly typed" program the "well-typed" subset of its least Herbrand model. This semantics is used to reason about partial correctness and absence of failures of correctly typed programs. The results are extended to programs with arithmetic.

*A preliminary, shorter version of this paper appeared in Apt and Gabbrielli [2].

1. INTRODUCTION

1.1. Motivation

The basic question we are trying to answer in this paper is: Can one reason about partial correctness (that is about the computed answer substitutions) of "natural" pure Prolog programs using the least Herbrand model semantics? We claim that the answer to this question is affirmative by showing that many logic programs and pure Prolog programs (i.e., logic programs using the leftmost selection rule) satisfy a property that implies that various declarative semantics of them are isomorphic.

Usually the declarative semantics of a logic program is identified with the least Herbrand model. When considering the class of all logic programs, there are a number of problems associated with this choice. First, this model depends on the underlying first-order language. For certain choices of this language this model is equivalent to the least term model, and for others not. Second, in general, it matches the procedural interpretation of logic programs only for ground queries, so the procedural behaviour of the program cannot be completely "retrieved" from this model.

The least term model of Clark [8] (or \(\mathcal{E}\)-semantics of Falaschi et al. [12]) is another natural candidate for the declarative semantics, and in fact it has been successfully used in the probably most elegant and compact proof of the strong completeness of the SLD resolution due to Stärk [19]. However, it shares the same deficiencies with the least Herbrand model.

The last choice is the \(\mathcal{P}\)-semantics proposed by Falaschi et al. [11]. This semantics provides a precise match with the procedural interpretation of logic programs, so it captures completely the procedural behaviour of the program. However, for specific programs it is rather laborious to construct and difficult to reason about.

We show here that for a large class of programs, called subsumption-free programs, these three semantics are in fact isomorphic. This allows us to reason about partial correctness and absence of failures of subsumption-free programs using the least Herbrand model. To prove that a program is subsumption-free we propose a semantic method based on the least Herbrand model. We also prove its equivalence with the method of Maher and Ramakrishnan [16] which is based on the \(\mathcal{P}\)-semantics. Using it we checked that several standard pure Prolog programs are subsumption-free.

However, for several natural programs, including APPEND, MEMBER, and other classical logic programs, the least Herbrand model is "overdefined" because it also includes facts with "ill-typed" arguments, whereas the program usually will be used only with "well-typed" arguments. As a result, the least Herbrand models are often tedious to construct and to reason about. This problem has to do with the fact that logic and Prolog programs are untyped, whereas in usual applications one uses these programs only with "well-typed" queries.

To remedy this problem we introduce yet another semantics, which consists of a "well-typed" fragment of the least Herbrand model. To define it we use types. We prove that this semantics, like the other three, admits a simple characterization in terms of fixpoints. Then we show how this semantics can be naturally used to reason about partial correctness and absence of failures of logic programs.

Finally, we extend these results to pure Prolog with arithmetic built-in's.
1.2. A Word on Terminology

Unless otherwise specified, we use the standard notation of logic programming. We consider here finite programs and queries w.r.t. a first-order language defined by a signature $\Sigma$. Given two expressions $E_1$ and $E_2$, we say that $E_1$ is more general than $E_2$ and write $E_1 \leq E_2$ if there exists a substitution $\theta$ such that $E_1\theta = E_2$. The relation $\leq$ is called the subsumption pre-ordering. If $E_1 \leq E_2$ but not $E_2 \leq E_1$, we write $E_1 < E_2$, and when both $E_1 \leq E_2$ and $E_2 \leq E_1$, we say that $E_1$ and $E_2$ are variants. Finally, we denote by $\text{Var}(E)$ the set of all variables occurring in the expression $E$.

A substitution is called grounding if all terms in its range are ground and is called a renaming if it is a permutation of the variables in its domain. We say that substitutions $\theta_1$ and $\theta_2$ are variants if for some renaming $\eta$ we have $\theta_1 = \theta_2\eta$. Below we shall freely use the well-known result that all mgu’s of two expressions are variants and that $E_1$ and $E_2$ are variants iff for some renaming $\eta$ we have $E_1 = E_2\eta$. Further, we denote by $\mathcal{B}$ the set of all atoms (the base of the language) and by $\mathcal{B}_g$ the set of all ground atoms.

For a number of reasons, we found it more convenient to work here with the concept of a query, correct and computed instance, and most general instance, instead of, respectively, the concepts of a goal, correct and computed answer substitution, and most general unifier. Moreover, we allow arbitrary mgu’s when forming resolvents in SLD derivations and use the notion of standardization apart as in Lloyd [14].

In short, a query is a finite sequence of atoms, denoted by letters $Q, A, B, C, \ldots$. Given a program $P$, $Q'$ is a correct instance of $Q$ if $P \models Q'$ and $Q' = Q\theta$ for a substitution $\theta$; $Q'$ is a computed instance of $Q$ if there exists a successful SLD derivation of $Q$ with a computed answer substitution $\theta$ such that $Q' = Q\theta$.

Our interest here is in finding, for a given program $P$, the set of computed instances of a query. In analogy to the case of imperative programs, we write $\{Q\}P\mathcal{C}$ to denote the fact that $\mathcal{C}$ is the set of computed instances of the query $Q$, and we denote the set of computed instances of the query $Q$ by $\text{sp}(Q, P)$ (for strongest postcondition of $Q$ w.r.t. $P$). So by definition $\{Q\}P\text{sp}(Q, P)$ for any $Q$ and $P$. Given two queries $Q$ and $Q'$, we write

$$\text{mgi}(Q, Q') = \{Q\theta | \theta \text{ is an mgu of } Q \text{ and } Q'\}.$$ 

So $\text{mgi}(Q, Q')$ is the set of most general instances of $Q$ and $Q'$.

A query is called separated if the atoms forming it are pairwise variable disjoint. Given a set of atoms $I$, we denote by $I^*$ the set of separated queries formed from the atoms of $I$. Given a query $Q$ and a set of atoms $I$, we write

$$\text{mgi}(Q, I) = \{Q\theta | \exists Q' \in I^*(\text{Var}(Q) \cap \text{Var}(Q') = \emptyset \land \theta \text{ is an mgu of } Q \text{ and } Q')\}.$$ 

So $\text{mgi}(Q, I)$ is the set of most general instances of $Q$ and any query from $I^*$ variable disjoint with $Q$. Finally, an atom is called pure if it is of the form $p(x_1, \ldots, x_n)$, where $x_1, \ldots, x_n$ are different variables.
2. BACKGROUND—THREE DECLARATIVE SEMANTICS

Three semantics of logic programs, each yielding a single model, were introduced in the literature and presented as "declarative." We review them now briefly and discuss their positive and problematic aspects.

2.1. The Least Herbrand Model ($\mathcal{H}$-Semantics)

This semantics was introduced by van Emden and Kowalski [22]. It associates with each program its least Herbrand model. Identifying each Herbrand model with the set of ground atoms true in it, we can equivalently define this semantics as

$$\mathcal{H}(P) = \{A \in \mathcal{B}_{H} | P \models A\}.$$

As van Emden and Kowalski [22] showed, this semantics can be characterized by means of the following immediate consequence operator defined on Herbrand interpretations:

$$T_p(I) = \{H \models B | H \leftarrow B \in \text{Ground}(P), I \models B\}.$$

More precisely, they established the following theorem.

Theorem 2.1 ($\mathcal{H}$-characterization)

(i) $T_p$ is continuous on the complete lattice of Herbrand interpretations ordered with $\subseteq$.

(ii) $\mathcal{H}(P)$ is the least fixpoint and the least pre-fixed point of $T_p$.

(iii) $\mathcal{H}(P) = T_p \uparrow \omega$.

In Section 8 we shall use an obvious generalization of this theorem to infinite programs.

As is well known, this semantics completely characterizes the operational behaviour of a program on ground queries because (see Apt and van Emden [5]), for a ground $Q$ a successful SLD derivation of $Q$ exists iff $Q \in \mathcal{H}(P)^\omega$. However, for nonground queries, the situation changes as the following example of Drabent and Maluszynski [10] shows.

Example 2.1. Consider two programs: $P_1$,

$$p(X).$$

and $P_2$,

$$p(a).$$

$$p(X).$$

Then $\mathcal{H}(P_1) = \mathcal{H}(P_2)$, but the query $p(X)$ yields different computed answer substitutions w.r.t. to each program.

So, in general, the $\mathcal{H}$-semantics does not characterize precisely the computed answers. This is an undesirable situation for program verification and analysis, because in these cases usually one needs to reason on the operational behaviour of programs in terms of their computed answers.
2.2. The Least Term Model ($\varepsilon$-Semantics)

This semantics was introduced by Clark [8] and more extensively studied in Falaschi et al. [12]. It associates with each program its least term model. Identifying each term model with the set of atoms true in it, we can equivalently define this semantics as

$$\varepsilon(P) = \{ A \in \mathcal{B} | P \models A \}.$$ 

Falaschi et al. [12] showed that this semantics also can be characterized by means of an operator defined on term interpretations:

$$U_p(I) = \{ H | \exists B_1 \cdots \exists B_n(H \leftarrow B_1, \ldots, B_n \in \text{inst}(P), \{ B_1, \ldots, B_n \} \subseteq I) \},$$

where $\text{inst}(P)$ denotes the set of all the instances of clauses in $P$. Then they established the following theorem analogous to the $\mathcal{M}$-characterization of Theorem 2.1.

**Theorem 2.2 ($\varepsilon$-characterization)**

(i) $U_p$ is continuous on the complete lattice of term interpretations ordered with $\subseteq$.

(ii) $\varepsilon(P)$ is the least pre-fixpoint and the least fixpoint of $U_p$.

(iii) $\varepsilon(P) = U_p \uparrow \omega$.

However, the $\varepsilon$-semantics cannot model the operational behaviour of a program either, because for Example 2.1 we have also $\varepsilon(P_1) = \varepsilon(P_2)$.

2.3. $\mathcal{P}$-Semantics

This semantics was introduced in Falaschi et al. [11]. For a survey on the $\mathcal{P}$-semantics and its uses, see Bossi et al. [7]. The aim of this semantics is to provide a precise match between the procedural and declarative interpretation of logic programs. Ideally, we would like to be able to "reconstruct" the procedural interpretation from the declarative one. Now, a procedural interpretation of a program $P$ can be identified with the set of all pairs $(Q, \theta)$, where $\theta$ is a computed answer substitution for $Q$, or, equivalently, with the set of all statements of the form $(Q)P \theta$.

The $\mathcal{P}$-semantics assigns to a program $P$ the set of atoms

$$\mathcal{P}(P) = \{ A \in \mathcal{B} | A \text{ is a computed instance of a pure atom} \}.$$ 

It seems at first sight that the restriction to pure atoms results in a "loss of information" and as a result the operational interpretation cannot be reconstructed from $\mathcal{P}(P)$. However, this is not so, as the following theorem of Falaschi et al. [11] shows.

**Theorem 2.3 (Strong completeness).** For a program $P$ and a query $Q$,

$$(Q)P \text{ mgi}(Q, \mathcal{P}(P)).$$

Consequently, by the form of $\mathcal{P}(P)$ we have the following corollary.
Corollary 2.1 (Full abstraction). For all programs \( P_1, P_2 \),
\[
\mathcal{S}(P_1) = \mathcal{S}(P_2) \quad \text{iff} \quad \text{sp}(Q, P_1) = \text{sp}(Q, P_2) \quad \text{for all queries } Q.
\]

An important property of the \( \mathcal{S} \)-semantics is that it can be defined by means of a fixpoint construction. More precisely, Falaschi et al. [11] introduced the following operator on term interpretations,
\[
T^\mathcal{S}_P(I) = \{ H \theta \mid \exists B, C(H \leftarrow B \in P, C \in I^*, \text{Var}(H \leftarrow B) \cap \text{Var}(C) = \emptyset, \theta \text{ is an mgu of } B \text{ and } C \}.
\]

and proved the following theorem.

Theorem 2.4 (\( \mathcal{S} \)-characterization)

(i) \( T^\mathcal{S}_P \) is continuous on the complete lattice of term interpretations ordered with \( \subseteq \).
(ii) \( \mathcal{S}(P) \) is the least fixpoint and the least pre-fixpoint of \( T^\mathcal{S}_P \).
(iii) \( \mathcal{S}(P) = T^\mathcal{S}_P \uparrow \omega \).

3. RELATING THEM

In what follows we wish to clarify the relationship between these three semantics for various classes of programs. To this end we introduce the following definition, where we view semantics as a function from the considered class of programs to some further unspecified semantic domain \( \mathcal{D} \).

Definition 3.1. Consider a class of program \( C \). We say that two semantics \( \mathcal{S}_1 \colon C \rightarrow \mathcal{D}_1 \) and \( \mathcal{S}_2 \colon C \rightarrow \mathcal{D}_2 \) are isomorphic on \( C \) iff there exist two functions \( \phi_1 \colon \mathcal{D}_1 \rightarrow \mathcal{D}_2 \) and \( \phi_2 \colon \mathcal{D}_2 \rightarrow \mathcal{D}_1 \) such that, for any program \( P \in C \),
\[
\mathcal{S}_1(P) = \phi_2(\mathcal{S}_2(P)) \quad \text{and} \quad \mathcal{S}_2(P) = \phi_1(\mathcal{S}_1(P)).
\]

Alternatively, two semantics \( \mathcal{S}_1 \colon C \rightarrow \mathcal{D}_1 \) and \( \mathcal{S}_2 \colon C \rightarrow \mathcal{D}_2 \), are isomorphic on \( C \) iff there exists a bijection \( \phi \colon \text{Range}(\mathcal{S}_1) \rightarrow \text{Range}(\mathcal{S}_2) \) such that, for any program \( P \in C \), \( \mathcal{S}_2(P) = \phi(\mathcal{S}_1(P)) \).

Every semantics \( \mathcal{S} \), for \( C \) induces an equivalence relation \( \approx_\mathcal{S} \) on programs from \( C \) defined by \( P_1 \approx_\mathcal{S} P_2 \) iff \( \mathcal{S}(P_1) = \mathcal{S}(P_2) \). Note that the notion of isomorphism also can be equivalently given in terms of equivalences by defining two semantics isomorphic on \( C \) if they induce the same equivalence relation on \( C \). When constructing isomorphisms between the semantics, the following operators will be useful.

Definition 3.2. Let \( I \) be a set of atoms. We define

(i) \( \text{Variant}(I) = \{ A \in \mathcal{D} \mid \exists B \in I \text{ s.t. } B \leq A \text{ and } A \leq B \} \), the set of variants.
(ii) \( \text{Up}(I) = \{ A \in \mathcal{D} \mid \exists B \in I \text{ s.t. } B \leq A \} \), the set of instances.
(iii) \( \text{Ground}(I) = \{ A \in \mathcal{D} \mid \exists B \in I \text{ s.t. } B \leq A \} \), the set of ground instances.
(iv) \( \text{Min}(I) = \{ A \in I \mid \exists B \in I \text{ s.t. } B < A \} \), the set of minimal (i.e., most general) elements.
(v) \( \text{True}(I) = \{ A \in \mathcal{D} \mid I \models A \} \), the set of atoms true in the Herbrand interpretation \( I \).
Note that Variant, Up, Ground, and Min are all idempotent. Moreover, the following statement clearly holds.

**Note 3.1.** For all $I$, $\text{Min}(\text{Up}(I)) = \text{Min}(I)$.

### 3.1. Relating $\mathcal{M}$-Semantics and $\mathcal{E}$-Semantics

We begin by clarifying the relationship between $\mathcal{M}(P)$ and $\mathcal{E}(P)$. The following result is an immediate consequence of the definitions.

**Note 3.2.** $\mathcal{M}(P) = \text{Ground}(\mathcal{E}(P))$.

Therefore, the $\mathcal{M}$-semantics can be reconstructed from the $\mathcal{E}$-semantics. The converse does not hold, in general, as the following argument due to Falaschi et al. [12] shows.

**Example 3.1.** Consider two programs: $P_1$, 

$\text{p}(\times)$. 

and $P_2$, 

$\text{p}(a)$. 

$\text{p}(b)$. 

defined w.r.t. the language with the signature $\Sigma = \{a/0, b/0\}$. Then $\mathcal{M}(P_1) = \mathcal{M}(P_2) = \{\text{p}(a), \text{p}(b)\}$, whereas $\mathcal{E}(P_1) = \{\text{p}(x), \text{p}(a), \text{p}(b)\}$ and $\mathcal{E}(P_2) = \{\text{p}(a), \text{p}(b)\}$.

In case the signature contains infinitely many constants, the situation changes, as the following result due to Maher [15] shows.

**Theorem 3.3.** Assume that the signature contains infinitely many constants. Then $\mathcal{E}(P) = \text{True}(\mathcal{M}(P))$.

**Proof.** We provide here an alternative, direct proof based on the theory of SLD resolution. The implication $\mathcal{E}(P) \subseteq \text{True}(\mathcal{M}(P))$ always holds, because $\mathcal{M}(P)$ is a model of $P$. Take now $A \in \text{True}(\mathcal{M}(P))$. Let $x_1, \ldots, x_n$ be the variables of $A$ and let $c_1, \ldots, c_n$ be distinct constants that do not appear in $P$ or $A$. Let $\theta = \{x_1/c_1, \ldots, x_n/c_n\}$. Then $A\theta \in \mathcal{M}(P)$. By the completeness of SLD resolution there exists a successful SLD derivation of $A\theta$ with the empty computed answer substitution. By replacing in it $c_i$ by $x_i$ for $i \in [1, n]$ we get a successful SLD derivation of $A$ with the empty computed answer substitution. Now by the soundness of SLD resolution, $A \in \mathcal{E}(P)$. $\square$

Consequently, when the signature contains infinitely many constants, the semantics $\mathcal{M}(P)$ and $\mathcal{E}(P)$ are isomorphic. We shall exploit this fact later.

### 3.2. Relating $\mathcal{E}$-Semantics and $\mathcal{A}$-Semantics

Next, we clarify the relationship between $\mathcal{E}(P)$ and $\mathcal{A}(P)$. First, we have the following result of Falaschi et al. [12].
Theorem 3.4. $\mathcal{G}(P) = \text{Up}(\mathcal{A}(P))$.

Therefore, the $\mathcal{G}$-semantics can be reconstructed from the $\mathcal{S}$-semantics. The converse does not hold, in general, as the following argument due to Falaschi et al. [11] shows.

Example 3.2. Consider the programs $P_1,$

$$p(x).$$

and $P_2,$

$$p(a) .$$

$$p(x).$$

of Example 2.1. Then $\mathcal{G}(P_1) = \mathcal{G}(P_2) = \text{Up}((p(x)))$, whereas $\mathcal{S}(P_1) = \text{Variant}((p(x)))$ and $\mathcal{S}(P_2) = \text{Variant}((p(x), p(a)))$. Note that the signature of the language was immaterial here.

Thus on the class of all programs, the $\mathcal{G}$-semantics and the $\mathcal{S}$-semantics are not isomorphic. In what follows we show that for a large class of programs they are, in fact, isomorphic. First, we have the following result.

Lemma 3.1. $\text{Min}(\mathcal{G}(P)) \subseteq \mathcal{S}(P)$.

Intuitively, Lemma 3.1 states that all most general atoms true in $\mathcal{G}(P)$ belong to $\mathcal{S}(P)$.

Proof. By Theorem 3.4, $\text{Min}(\mathcal{G}(P)) = \text{Min}(\text{Up}(\mathcal{A}(P)))$ and the claim follows by Note 3.1, because for all $I$, we have $\text{Min}(I) \subseteq I$. □

In general, the converse inclusion does not hold.

Example 3.3. Consider the following program $P,$

$$p(a).$$

$$p(X).$$

defined w.r.t. the language with the signature $\Sigma = \{a/0\}$. Then $\mathcal{S}(P) = \text{Variant}((p(y))) \cup (p(a))$, whereas $\text{Min}(\mathcal{G}(P)) = \text{Variant}((p(y)))$.

A closer examination of the situation reveals the following information: By the soundness of the SLD resolution we always have $\mathcal{S}(P) \subseteq \mathcal{G}(P)$. Example 3.3 shows that the stronger inclusion $\mathcal{S}(P) \subseteq \text{Min}(\mathcal{G}(P))$ does not need to hold. The reason is that $\mathcal{S}(P)$ can contain a pair $A, B$ such that $A$ strictly subsumes $B$ (i.e., $A < B$). This cannot happen when $\mathcal{S}(P)$ contains only minimal elements, so we are brought to the following definition due to Maher and Ramakrishnan [16].

Definition 3.3. A set of atoms $I$ is called subsumption-free if $\text{Min}(I) = I$. A program $P$ is called subsumption-free if $\mathcal{S}(P)$ is.

We now show that the notion of a subsumption-free program is a key for establishing the converse of Lemma 3.1.
Theorem 3.5. $\mathcal{A}(P) = \operatorname{Min}(\mathcal{S}(P))$ iff $P$ is subsumption-free.

Proof. ($\Rightarrow$) We have

\[
\operatorname{Min}(\mathcal{S}(P)) = \{\text{assumption}\}
\operatorname{Min}(\operatorname{Min}(\mathcal{S}(P))) = \{\text{idempotence of Min}\}
\operatorname{Min}(\mathcal{S}(P)) = \{\text{assumption}\}
\mathcal{A}(P).
\]

($\Leftarrow$) We have

\[
\mathcal{A}(P) = \{\text{assumption}\}
\operatorname{Min}(\mathcal{S}(P)) = \{\text{Note 3.1}\}
\operatorname{Min}(\operatorname{Up}(\mathcal{A}(P))) = \{\text{Theorem 3.4}\}
\operatorname{Min}(\mathcal{S}(P)).
\]

Consequently, the $\mathcal{S}$-semantics and $\mathcal{A}$-semantics are isomorphic on subsumption-free programs. Additionally, when the signature contains infinitely many constants, all three semantics are isomorphic. Combining Theorems 2.3, 3.3 and 3.5 we thus obtain the following corollary.

Corollary 3.1. Assume that the signature contains infinitely many constants. Then for a subsumption-free program $P$ and a query $Q$,

\[
\{Q\}P \operatorname{mgI}(Q, \operatorname{Min}(\operatorname{True}(\mathcal{A}(P))).
\]

Corollary 3.1 shows that computed answers of subsumption-free programs can be fully reconstructed from the $\mathcal{A}$-semantics using unification and, therefore, the least Herbrand model can be used to reason about partial correctness.

The point of view taken in this paper is that the $\mathcal{A}$-semantics is handier than the $\mathcal{S}$-semantics for reasoning about partial correctness. By the $\mathcal{A}$-characterization of Theorem 2.1 and the $\mathcal{S}$-characterization of Theorem 2.4, both $\mathcal{A}(P)$ and $\mathcal{A}(P)$ are obtained as the $\omega$ power of a suitable monotonic operator associated with the program under consideration and, therefore, a natural form of inductive reasoning can be adopted to construct either semantics. However, in the case of $\mathcal{S}$-semantics, it is necessary to deal with sets of nonground atoms, which entails dealing with general substitutions of variables with nonground terms—a process that may be very elaborate in practice. Moreover, for a large class of programs it is possible to show that a given interpretation coincides with the $\mathcal{A}$-semantics in a straightforward way, without using inductive arguments. This technique is briefly discussed in Section 6.
On the other hand, the $\mathcal{S}$-semantics is in general more compact than the $\mathcal{K}$-semantics. For instance, the $\mathcal{S}$-semantics of both programs given in Example 2.1 is a finite set (modulo variable renaming), whereas the $\mathcal{K}$-semantics of both such programs is infinite (albeit easy to describe in an infinitary language) when the signature contains infinitely many constants. However, this advantage of the $\mathcal{S}$-semantics is hardly useful when conducting “paper and pencil” proofs of partial correctness, due to the complications arising from manipulation of arbitrary substitutions. In the next section we shall identify a smaller class of programs for which this characterization of partial correctness does not involve unification.

Of course, if we do not make any assumption on the class of programs $\mathcal{C}$, subsumption-freedom is only a sufficient condition for the isomorphism of the $\mathcal{C}$-semantics and $\mathcal{S}$-semantics. Indeed, when the class of programs consists of just the program from Example 3.3, which is not subsumption-free, then the $\mathcal{C}$-semantics and $\mathcal{S}$-semantics are obviously isomorphic. However, for a “reasonably large” class of programs, subsumption-freedom turns out to be also a necessary condition for isomorphism of programs.

Definition 3.4. A class of programs $\mathcal{C}$ is $\mathcal{S}$-closed if, for every program $P$ in $\mathcal{C}$, every finite subset of $\mathcal{S}(P)$ is in $\mathcal{C}$.

Indeed, we have the following result.

NOTE 3.6. For an $\mathcal{S}$-closed class $\mathcal{C}$ of programs, the $\mathcal{C}$-semantics and $\mathcal{S}$-semantics are isomorphic on $\mathcal{C}$ iff $\mathcal{C}$ is a class of subsumption-free programs.

PROOF. ($\Rightarrow$) Suppose that some $P \in \mathcal{C}$ is not subsumption-free. Then for some atoms $A, B \in \mathcal{S}(P)$ we have $A < B$. By the definition of $\mathcal{S}$-closedness, both $P_1 = \{A, B\}$ and $P_2 = \{A\}$ are in $\mathcal{C}$. Now $\mathcal{S}(P_1) = \text{Up}([A, B]) = \text{Up}([A]) = \mathcal{S}(P_2)$, whereas $\mathcal{S}(P_1) = \text{Variant}([A, B]) \neq \text{Variant}([A]) = \mathcal{S}(P_2)$. Contradiction.

($\Leftarrow$) This is the contents of Theorems 3.4 and 3.5. $\square$

The foregoing proof shows that the notion of subsumption-freedom is crucial for our considerations. In what follows we provide some means of establishing that a program is subsumption-free.

4. REDUNDANCY-FREE PROGRAMS

We begin by studying a subclass of subsumption-free programs.

Definition 4.1. A program $P$ is called redundancy-free iff $\mathcal{S}(P)$ does not contain a pair of nonvariant unifiable atoms.

Clearly, redundancy-freedom implies subsumption-freedom, because $\mathcal{S}(\mathcal{S})$ is closed under renaming and $A < B$ implies that $A$ and a variant $B'$ of $B$ are nonvariant and unifiable. The converse does not hold.

Example 4.1. Consider the following program $P$ defined w.r.t. the language with the signature $\Sigma = \{a / 0\}$:

\[
p(X, a).
\]

\[
p(a, X).
\]
Then \( \mathcal{A}(P) = \text{Variant}(\{p(x, a), p(a, x)\}) \), so \( P \) is not redundancy-free. However, it is clearly subsumption-free because the atoms \( p(x, a) \) and \( p(a, x) \) are not comparable in the subsumption pre-ordering.

The following theorem summarizes the difference between the subsumption-free and redundancy-free programs in a succinct way. Let us extend the Min operator in an obvious way to sets of queries.

**Theorem 4.1**

(i) \( P \) is subsumption-free iff for all pure atoms \( A \), \( \text{Min}(\text{sp}(A, P)) = \text{sp}(A, P) \).

(ii) \( P \) is redundancy-free iff for all queries \( Q \), \( \text{Min}(\text{sp}(Q, P)) = \text{sp}(Q, P) \).

**Proof.** (i) Note that for some variables \( x_1, x_2, \ldots \), \( \mathcal{A}(P) \) is a disjoint union of sets of the form \( \text{sp}(p(x_1, \ldots, x_{\text{arity}(p)}), P) \) and that atoms belonging to different such sets are incomparable in the \( \leq \) pre-ordering. Thus \( \text{Min}(\mathcal{A}(P)) \) is a disjoint union of sets of the form \( \text{Min}(\text{sp}(p(x_1, \ldots, x_{\text{arity}(p)}), P)) \).

(ii) (\( \Rightarrow \)) Consider two computed instances \( Q_1 \) and \( Q_2 \) of \( Q \). By Theorem 2.3 there exist \( C_1 \) and \( C_2 \) in \( \mathcal{S}(P) \) such that, for \( i \in [1, 2] \), \( Q \) and \( C_i \) are variable disjoint and

\[
Q_i \in \text{mgi}(Q, C_i). \quad (4.1)
\]

In particular, \( C_1 \leq Q_1 \) and \( C_2 \leq Q_2 \).

Suppose now that \( Q_1 < Q_2 \). Then \( C_1 \leq Q_2 \), so \( Q_2 \) is an instance of both \( C_1 \) and \( C_2 \). Because we may assume that \( C_1 \) and \( C_2 \) are variable disjoint, we conclude that \( C_1 \) and \( C_2 \) are unifiable. By assumption about \( P \) and the fact that \( C_1 \) and \( C_2 \) are separated queries, \( C_1 \) and \( C_2 \) are variants. This implies by (4.1) that \( Q_1 \) and \( Q_2 \) are variants, as well. Contradiction.

(\( \Leftarrow \)) Suppose that \( \mathcal{A}(P) \) does contain a pair \( A, B \) of nonvariant unifiable atoms. Let \( C \in \text{mgi}(A, B) \). Then \( A \leq C \) and \( B \leq C \) and at least one of these subsumption relations, say the first one, is strict, so \( A < C \). Take now a variant \( A' \) of \( A \) variable disjoint with \( A \) and \( B \). By Theorem 2.3 \( A, C \in \text{sp}(A', P) \), so \( \text{Min}(\text{sp}(A', P)) \neq \text{sp}(A', P) \). Contradiction. \( \square \)

For redundancy-free programs we can simplify the formulation of Corollary 3.1.

**Corollary 4.1.** Consider a redundancy-free program \( P \) and a query \( Q \). Then:

(i) \( \{Q\}P \text{Min}(\{Q\theta | P \models \theta\}) \).

(ii) \( \{Q\}P \text{Min}(\{Q\theta | \mathcal{E}(P) \models \theta\}) \).

(iii) If the signature contains infinitely many constant symbols,

\[
\{Q\}P \text{Min}(\{Q\theta | \mathcal{M}(P) \models \theta\})
\]

**Proof.** (i) follows from Theorem 4.1(ii) and the following two claims.

**Claim 1.** For an arbitrary program \( P \) and a query \( Q \),

\[
\text{Min}(\{Q\theta | P \models \theta\}) \subseteq \text{sp}(Q, P) \subseteq \{Q\theta | P \models \theta\}.
\]

**Proof.** Take \( Q_1 \in \text{Min}(\{Q\theta | P \models \theta\}) \). By the strong completeness of SLD resolution, there exists a computed instance \( Q_2 \) of \( Q_1 \) such that \( Q_2 \leq Q_1 \). By the choice
of \( Q_1, \, P \models Q_2 \), so by the minimality of \( Q_1, \, Q_1 \) and \( Q_2 \) are variants. Thus \( Q_1 \) is also a computed instance of \( Q \), i.e., \( Q_1 \in \text{sp}(Q, \, P) \). \( \Box \)

**Claim 2.** For two sets of queries \( \mathcal{C}_1 \) and \( \mathcal{C}_2 \), if \( \text{Min}(\mathcal{C}_1) \subseteq \mathcal{C}_2 \subseteq \mathcal{C}_1 \) and \( \text{Min}(\mathcal{C}_2) = \mathcal{C}_2 \), then \( \mathcal{C}_2 = \text{Min}(\mathcal{C}_1) \).

The proof is immediate.

Now (ii) is a straightforward consequence of (i) and the definition of the \( \mathcal{C} \)-semantics. Finally, (iii) follows from (ii) and Theorem 3.3. \( \Box \)

So for redundancy-free programs the sets of computed instances can be defined without the use of unification.

The following result provides a method based on the least Herbrand model, which allows us to conclude that a program is redundancy-free, so a fortiori it is subsumption-free.

**Theorem 4.2.** Suppose that the following conditions hold for a program \( P \):

1. **SEM1.** If \( H \leftarrow B_1 \) and \( H \leftarrow B_2 \) are ground instances of two different clauses in \( P \), then
   \[ \mathcal{M}(P) \not\models B_1 \land B_2. \]

2. **SEM2.** If \( H \leftarrow B_1 \) and \( H \leftarrow B_2 \) are distinct ground instances of the same clause in \( P \), then
   \[ \mathcal{M}(P) \not\models B_1 \land B_2. \]

Then \( P \) is redundancy-free.

**PROOF.** We shall need the following observation.

**Claim 1.** Let \( \xi \) be an SLD-refutation of a query and a program \( P \) and let \( \vartheta \) be the composition of the mgu's used in \( \xi \). If \( H \leftarrow B \) is an input clause used in \( \xi \), then
\[ \mathcal{M}(P) \models B \vartheta. \]

**PROOF.** We have \( \vartheta = \vartheta_1 \vartheta_2 \), where \( \vartheta_1 \) is the composition of the mgu's used in \( \xi \) until \( H \leftarrow B \) is used, and \( \vartheta_2 \) is the composition of the mgu's used in \( \xi \) from that moment on. By the soundness theorem for SLD-resolution,
\[ \mathcal{M}(P) \models B \vartheta_2, \]
but by the standardization part \( B \vartheta_1 = B \), so in fact
\[ \mathcal{M}(P) \models B \vartheta, \]
which concludes the proof. \( \Box \)

We prove now the contrapositive. Assume that the program \( P \) is not redundancy-free. By Theorem 4.1 there exists a query \( Q \) that admits two computed instances \( Q' \) and \( Q'' \) such that \( Q' < Q'' \). Consider then two SLD-refutations \( \xi' \) and \( \xi'' \) for \( Q \) which use the same selection rule, yielding the computed instances \( Q' = Q_\gamma \) and \( Q'' = Q_\delta \), where \( \gamma \) and \( \delta \) are the compositions of the mgu's used in \( \xi' \) and \( \xi'' \), respectively. Note that, by a suitable choice of the variants of the
clauses used in $\xi'$ and $\xi''$, we can assume without loss of generality that $Q'$ and $Q''$ are variable disjoint and thus unifiable.

Let $c_1, \ldots, c_n$ ($n \geq 1$) be the sequence of clauses of $P$ used in $\xi'$ and let $d_1, \ldots, d_m$ ($m \geq 1$) be the sequence of clauses of $P$ used in $\xi''$. Next, consider $k$ ($1 \leq k \leq \min(n, m)$) such that

$$c_i = d_i, \quad \text{for } i \in [1, k-1],$$

$$c_k \neq d_k.$$

Observe that $k$ exists, since $Q'$ and $Q''$ are not variants. Assume that $H' \leftarrow B'$ is the variant of $c_k$ used as input clause in $\xi'$ and $H'' \leftarrow B''$ is the variant of $d_k$ used as input clause in $\xi''$. The following two cases arise.

**Case 1** ($H'\gamma$ and $H''\delta$ unify). By the definition of a unifier there exists a ground instance $H \leftarrow B_1$, of $(H' \leftarrow B')\gamma$ and a ground instance $H \leftarrow B_2$, of $(H'' \leftarrow B'')\delta$, where $H$ is a common ground instance of $H'\gamma$ and $H''\delta$. From Claim 1 it follows $\mathcal{A}(P) \models B_1 \land B_2$, and consequently $P$ does not satisfy condition SEM1.

**Case 2** ($H'\gamma$ and $H''\delta$ do not unify). In this case let $R_1, \ldots, R_k$ be the first $k$ resolvents of both SLD refutations, so $R_1 = Q$ and, for $i \in [2, k]$, $R_i$ is obtained from $R_{i-1}$ by using the clause $c_{i-1}$ ($= d_{i-1}$). Let $A$ be the selected atom in $R_k$.

From the definition of $\gamma$, $\delta$, $c_k$, and $d_k$ it follows that $A\gamma = H'\gamma$ and $A\delta = H''\delta$. Therefore, the nonunifiability of $H'\gamma$ and $H''\delta$ implies that $R_k\gamma$ and $R_k\delta$ are not unifiable. On the other hand, by the previous assumption, $R_1\gamma$ (= $Q'$) and $R_1\delta$ (= $Q''$) are unifiable.

Thus there exists an index $j \in [2, k]$ such that

$$R_i\gamma \text{ and } R_i\delta \text{ unify for } i \in [1, j-1],$$

$$R_j\gamma \text{ and } R_j\delta \text{ do not unify.} \quad (4.2)$$

Let $c_j$ be of the form $K \leftarrow B$. Because nonrelevant mgu's can be used in the SLD derivation, we can assume without loss of generality that

$$\text{Var}(K \leftarrow B) \cap \text{Var}(K \leftarrow B) = \emptyset. \quad (4.3)$$

From the definition of the $R_i$s and from (4.2) it follows that $K\gamma$ and $K\delta$ unify, whereas $B\gamma$ and $B\delta$ are not unifiable. This, together with (4.3), implies that there exist two different ground instances $H \leftarrow B_1$ and $H \leftarrow B_2$ of the clauses $(K \leftarrow B)\gamma$ and $(K \leftarrow B)\delta$, and hence of the clause $K \leftarrow B$, such that $H$ is a common ground instance of $K\gamma$ and $K\delta$. Again from Claim 1 it follows $\mathcal{A}(P) \models B_1 \land B_2$. Consequently, $P$ does not satisfy condition SEM2 and this completes the proof. □

If $H \leftarrow B_1$ and $H \leftarrow B_2$ are ground instances of clauses in $P$, then clearly $\mathcal{A}(P) \not\models B_1 \land B_2$ iff $\mathcal{A}(P) \not\models H \land B_1 \land B_2$. Therefore, in some cases we shall consider the formulation of SEM1 and SEM2 that uses $\mathcal{A}(P) \not\models H \land B_1 \land B_2$, because this will simplify the reasoning. It is also easy to see that SEM1 and SEM2 are, respectively, implied by the following two conditions:

**SYN.** No variable disjoint variants of two clause heads of $P$ unify.

**SEM.** If $H \leftarrow B_1$, $H \leftarrow B_2 \in \text{Ground}(P)$ and $B_1 \neq B_2$, then $\mathcal{A}(P) \not\models B_1 \land B_2$.

Note that condition SEM alone does not ensure subsumption-freedom (and hence, a fortiori, redundancy-freedom), as the program $(p(X)., p(a).)$ shows.
Maher and Ramakrishnan [16] studied subsumption-free programs in the context of the bottom up computation in deductive databases and showed that for these programs this computation can be performed more efficiently. They proved that the class of redundancy-free programs is Turing complete. They also provided two conditions ensuring redundancy-freedom. One was based on \( \mathcal{R}(P) \) and, using our terminology, is exactly condition SEM2 used above. The other condition was based on the \( \mathcal{S} \)-semantics and can be expressed as follows:

SEM1'. If \( c \) and \( d \) are different clauses in \( P \), then no pair \( A \in T_{(c)}(\mathcal{S}(P)) \) and \( B \in T_{(d)}(\mathcal{S}(P)) \) is unifiable.

Interestingly, the simpler condition SEM1 turns out to be equivalent to SEM1'. This is the content of the following lemma.

**Lemma 4.1.** For a program \( P \), SEM1' holds iff SEM1 holds.

**Proof.** We prove the contrapositive for both implications.

(\( \Rightarrow \)) Assume that SEM1 does not hold. Then there exist two ground instances 
\((H_1 \leftarrow B_1, \eta_1)\) and \((H_2 \leftarrow B_2, \eta_2)\) of two different clauses \( c: H_1 \leftarrow B_1 \) and \( d: H_2 \leftarrow B_2 \) in \( P \), such that \( \mathcal{S}(P) \models B_1, \eta_1 \land B_2, \eta_2 \) and \( H_1, \eta_1 = H_2, \eta_2 \). However, \( \mathcal{S}(P) = \text{Ground}(\mathcal{S}(P)) \), so there exist some \( C_1 \in \mathcal{S}(P)^* \), \( C_2 \in \mathcal{S}(P)^* \), \( \gamma_1 \), and \( \gamma_2 \) such that

\[
B_1, \eta_1 = C_1, \gamma_1, \quad (4.4) \\
B_1, \eta_2 = C_2, \gamma_2. \quad (4.5)
\]

We can assume without loss of generality that \( H_i \leftarrow B_i \) and \( C_i \) do not share variables, for \( i \in [1, 2] \). Therefore, (4.4) and (4.5) imply that there exists \( \delta_1, \delta_2, \beta_1, \) and \( \beta_2 \) such that

\[
\delta_1 \text{ is a relevant mgu of } B_1 \text{ and } C_1, \quad H_1, \eta_1 = H_1, \delta_1 \beta_1, \quad (4.6) \\
\delta_2 \text{ is a relevant mgu of } B_2 \text{ and } C_2, \quad H_2, \eta_2 = H_2, \delta_2 \beta_2. \quad (4.7)
\]

Consider now \( A = H_1, \delta_1 \) and \( B = H_2, \delta_2 \). From (4.6) and (4.7) it follows that \( A \in T_{(c)}(\mathcal{S}(P)) \) and \( B \in T_{(d)}(\mathcal{S}(P)) \). In order to show that \( A \) and \( B \) are unifiable, note that, again without loss of generality, we can assume \( \text{Var}(H_i) \cap \text{Var}(H_j - B_j) = \emptyset \) and \( \text{Var}(H_i) \cap \text{Var}(C_i) = \emptyset \), for \( i, j \in [1, 2], i \neq j \). From the fact that the mgu's \( \delta_i \) are relevant, it follows that also \( H_i, \delta_1 \) and \( H_i, \delta_2 \) do not share variables. Therefore, from the assumption \( H_1, \eta_1 = H_2, \eta_2 \), (4.6), and (4.7) it follows that \( H_1, \delta \) and \( H_2, \delta \) are unifiable. Thus condition SEM1' does not hold.

(\( \Leftarrow \)) Assume that SEM1' does not hold. Then there exists a pair \( A \in T_{(c)}(\mathcal{S}(P)) \) and \( B \in T_{(d)}(\mathcal{S}(P)) \) which is unifiable, where \( c: H_1 \leftarrow B_1 \) and \( d: H_2 \leftarrow B_2 \) are two different clauses in \( P \). Then for some \( C_1 \in \mathcal{S}(P)^* \), \( C_2 \in \mathcal{S}(P)^* \), and \( \delta_1, \delta_2 \),

\[
A = H_1, \delta_1, \quad \text{Var}(H_1 \leftarrow B_1) \cap \text{Var}(C_1) = \emptyset, \quad \delta_1 \text{ is an mgu of } B_1 \text{ and } C_1, \\
B = H_2, \delta_2, \quad \text{Var}(H_2 \leftarrow B_2) \cap \text{Var}(C_2) = \emptyset, \quad \delta_2 \text{ is an mgu of } B_2 \text{ and } C_2.
\]

Because \( A \) and \( B \) are unifiable there exists an \( \eta \) such that \( H_1, \delta_1 \eta = H_2, \delta_2 \eta \) and \( (H_1 \leftarrow B_1), \eta_1 \), \((H_2 \leftarrow B_2), \eta_2 \) are ground instances of \( c \) and \( d \), respectively. Note 3.2 and Theorem 3.4 imply \( \mathcal{S}(P) = \text{Ground}(\mathcal{S}(P)) \). Therefore,

\[
\mathcal{S}(P) = B_1, \delta_1 \eta \land B_2, \delta_2 \eta,
\]
because \( C_i \in \mathcal{S}(P)^* \) and \( B_i, B_i = C_i, B_i \) for \( i \in [1, 2] \). Consequently SEM1 does not hold and this completes the proof. \( \square \)

Let us discuss now the conditions of Theorem 4.2. It is obvious that conditions SEM1 and SEM2 are only sufficient for proving that a program is redundancy-free. Indeed, adding to a program a variant of its clause does not change any of its semantics, so a fortiori its redundancy-freedom status, but it invalidates the SEM1 condition.

To deal with such problems, consider the following strengthening of the equivalent condition SEM1':

\[
\text{SEMI}''. \text{ If } c \text{ and } d \text{ are different clauses in } P, \text{ then no pair } A \in T_{c}(\mathcal{S}(P)) \text{ and } B \in T_{d}(\mathcal{S}(P)) \text{ is unifiable, unless } A \text{ and } B \text{ are variants.}
\]

Theorem 4.2 remains valid when SEM1 is replaced by SEMI'', because essentially the same proof as in [16] holds. This strengthening of SEM1 is of use not only for “artificial” programs, namely, consider the following program ISO_TREE:

\[
\begin{align*}
is(\text{void}, \text{void}). \\
is(\text{tree}(X, \text{Left}1, \text{Right}1), \text{tree}(X, \text{Left}2, \text{Right}2)) & \leftarrow \\
& \hspace{1cm} is(\text{Left}1, \text{Left}2), is(\text{Right}1, \text{Right}2). \\
is(\text{tree}(X, \text{Left}1, \text{Right}1), \text{tree}(X, \text{Left}2, \text{Right}2)) & \leftarrow \\
& \hspace{1cm} is(\text{Left}1, \text{Right}2), is(\text{Right}1, \text{Left}2).
\end{align*}
\]

from Sterling and Shapiro ([20], p. 58), which tests whether two binary trees are isomorphic. Clearly, condition SEM2 is satisfied by ISO_TREE, because actually its stronger version SYN2 defined at the end of this section holds, but SEMI does not hold because

\[
is(\text{tree}(\text{void}, \text{void}, \text{void}), \text{tree}(\text{void}, \text{void}, \text{void})) \leftarrow \\
\hspace{1cm} is(\text{void}, \text{void}), is(\text{void}, \text{void}).
\]

is a ground instance of both the second and the third clause of ISO_TREE and clearly

\[
\models_{\text{ISO_TREE}} \models is(\text{void}, \text{void}), is(\text{void}, \text{void})
\]

holds, However, condition SEMI'' does hold. Indeed, define by induction a most general tree (mgt) as follows: void is a mgt. If \( t_1 \) and \( t_2 \) are variable disjoint mgt's and \( X \) is a variable that appears neither in \( t_1 \) nor in \( t_2 \), then \( \text{tree}(X, t_1, t_2) \) is a mgt.

The following observations follow from the definitions by a straightforward inductive argument:

(i) If \( is(t_1, t_2) \in \mathcal{S}(\text{ISO_TREE}) \), then \( t_1 \) and \( t_2 \) are mgt's.
(ii) If \( t_1 \) and \( t_2 \) are unifiable mgt's, then they are variants.

In order to show that SEMI'' holds for the program ISO_TREE, let us consider two atoms \( A \in T_{c}(\mathcal{S}(\text{ISO_TREE})) \) and \( B \in T_{d}(\mathcal{S}(\text{ISO_TREE})) \), where \( c: H_2 \leftarrow B_2 \) is the second clause and \( d: H_3 \leftarrow B_3 \) is the third clause. Assume that
iso(t_1, t_2), iso(t_3, t_4), iso(l_1, l_2), and iso(l_3, l_4) are pairwise variable disjoint atoms in \( S(ISO_{-}\text{TREE}) \) such that

\[ \vartheta_2 \text{ is an mgu of } B_2 \text{ and } iso(t_1, t_2), iso(t_3, t_4), \]
\[ \vartheta_3 \text{ is an mgu of } B_3 \text{ and } iso(l_1, l_2), iso(l_3, l_4), \]

and \( A = H\vartheta_2, B = H\vartheta_3 \). Then

\[ A = iso(\text{tree}(x, t_1, t_3), \text{tree}(X, t_2, t_4)), \]
\[ B = iso(\text{tree}(y, l_1, l_3), \text{tree}(Y, l_4, l_2)). \]

If \( A \) and \( B \) unify, from (i) and (ii) above and an easy inspection of the unification algorithm it follows that \( A \) and \( B \) are variants. So SEM1' holds and ISO_{-}\text{TREE} is redundancy-free.

In certain situations the conditions of Theorem 4.2 can be ensured by means of syntactic restrictions, namely, condition SEM1 is obviously implied by the following condition:

SYN1. If \( H_1 \leftarrow B_1 \) and \( H_2 \leftarrow B_2 \) are variable disjoint variants of different clauses in \( P \), then \( H_1 \) and \( H_2 \) do not unify.

In addition, condition SEM2 is automatically satisfied when the following condition holds:

SYN2. If \( H \leftarrow B \in P \), then \( Var(B) \subseteq Var(H) \).

Note that the qualification "variable disjoint variants" cannot be dropped from SYN1. Indeed, consider the program \( P \)

\[ p(X). \]
\[ p(f(X)). \]

Then for \( P \) this modification of SYN1 holds, but SEM1 does not hold.

It is worth mentioning that an immediate proof of Turning completeness for redundancy-free programs can be obtained by using the encoding of two register machines into pure logic programs given in Shepherdson [18]. In fact, conditions SYN1 and SYN2 readily apply to programs obtained by such an encoding. In the next section we assess the applicability of Theorem 4.2.

5. CHECKING REDUNDANCY-FREEDOM

We provide here four illustrative uses of Theorem 4.2.

Example 5.1.

(i) Consider first the proverbial APPEND program:

\[ \text{append}([], Ys, Ys). \]
\[ \text{append}([X|Xs], Ys, [X|Zs]) \leftarrow \text{append}(Xs, Ys, Zs). \]

Here the syntactic conditions SYN1 and SYN2 readily apply.

(ii) Consider now the SUFFIX program:

\[ \text{suffix}(Xs, Xs). \]
\[ \text{suffix}(Xs, [Y|Ys]) \leftarrow \text{suffix}(Xs, Ys). \]
Note that the heads of the clauses unify, so we cannot use condition SYN1. To prove condition SEM1 we reason as follows. Denote by OCC the set of ground atoms of the form suffix(s, t_s) where t_s is a term containing the term s. By definition of $T_p$, $T_{\text{suffix}}(\text{OCC}) \subseteq \text{OCC}$, i.e., OCC is a pre-fixpoint of $T_{\text{suffix}}$. By the $\mathcal{A}$-characterization Theorem 2.1, $\mathcal{A}(\text{SUFFIX}) \subseteq \text{OCC}$, so, for any ground instance

$$\text{suffix}(t_1, [t_2|t_3]) \iff \text{suffix}(t_1, t_3)$$

of the second clause, if $\mathcal{A}(\text{SUFFIX}) \models \text{suffix}(t_1, t_3)$, then $t_1$ and $[t_2|t_3]$ are different terms. Thus $\text{suffix}(t_1, [t_2|t_3])$ is not an instance of the first clause and consequently SEM1 holds.

The clauses of SUFFIX do not contain variables, so condition SYN2 applies.

(iii) Consider now the naive REVERSE program:

- reverse([], []).
- reverse([X|Xs], Zs) $\iff$ reverse(Xs, Ys),
  append(Ys, [X], Zs)

(augmented by the APPEND program.

The heads of different clauses do not unify, so condition SYN1 applies. However, due to presence of the local variable Ys in the second clause, condition SYN2 does not apply. To prove condition SEM2 we analyze the least Herbrand model $\mathcal{A}(\text{REVERSE})$. Using the list constructor binary function $[\ldots]$ let us define the notation $[t_1|t_2|\ldots|t_n]$ for $n \geq 2$ by induction as follows. For $n = 2$, $[t_1|t_2]$ is the induction base. For $n > 2$, we define by induction,

$$[t_1|t_2|\ldots|t_n] = [t_1|[t_2|\ldots|t_n]].$$

A list is then defined as either the constant symbol $[\ ]$ (the empty list) or a construct of the form $[t_1|t_2|\ldots|t_n]$, where $n \geq 2$ and $t_n = [\ ]$. Finally, given a list s and a term t, we define their concatenation $s*t$ as follows:

If $s = [\ ]$, then $s*t = t$.
If $s = [t_1|\ldots|t_{n-1}|[\ ]], then s*t = [t_1|\ldots|t_{n-1}|[t].$

Then it can be shown that

$$\mathcal{A}(\text{APPEND}) = \{\text{append}(s, t, u) | s \text { is a ground list, }$$

$$t \text { is a ground term and } s*t=u\}$$

and

$$\mathcal{A}(\text{REVERSE}) = \{\text{reverse}(s,t) | s, t \text{ are ground lists and } t=\text{rev}(s)\}$$

$\cup \mathcal{A}(\text{APPEND}),$

where given a list s, rev(s) denotes its reverse.

Take now a ground instance

reverse([x|xs], zs) $\iff$ reverse(xs, ys),
append(ys, [x], zs)

of the second clause with reverse([x|xs], zs) in $\mathcal{A}(\text{REVERSE})$. Then reverse(xs, ys) $\in \mathcal{A}(\text{REVERSE})$ implies ys=rev(xs), so condition
SEM2 holds for this clause. For other clauses condition SYN2 applies. We conclude that REVERSE is redundancy-free.

(iv) Finally, consider the following program HANOI from Sterling and Shapiro [20], which, for the query \( \text{hanoi}(n, a, b, c, \text{Moves}) \), solves the "Towers of Hanoi" problem with \( n \) disks and three pegs \( a, b, \) and \( c \) giving the sequence of moves forming the solution in \( \text{Moves} \):

\[
\begin{align*}
\text{hanoi}(s(0), A, B, C, [A \text{ to } B]). \\
\text{hanoi}(s(N), A, B, C, \text{Moves}) &\leftarrow \\
\text{hanoi}(N, A, C, B, \text{Ms1}) \\
\text{Hanoi}(N, C, B, A, \text{Ms2}) \\
\text{append}(\text{Ms1}, [A \text{ to } B | \text{Ms2}], \text{Moves}).
\end{align*}
\]

Note that conditions SYN1 and SYN2 do not apply here. To prove condition SEM1, first note that \(~', (\text{HANOI})\# \text{hanoi}(t_1, t_2, t_3, t_4, t_5)\) implies \( t_1 \neq 0 \). Hence for any ground instance \( \text{hanoi}(t_1, t_2, t_3, t_4, t_5) \leftarrow B \) of the second clause, if \( t_1 = s(0) \), then \(~'(\text{HANOI}) \# B\). This implies SEM1.

To prove condition SEM2 we use the methodology of Maher and Ramakrishnan [16] based on functional dependencies. First we need a definition.

**Definition 5.1.** Let \( p \) be an \( n \)-ary relation symbol. A functional dependency is a construct of the form \( p[I \rightarrow J] \), where \( I, J \subseteq \{1, \ldots, n\} \). Let \( M \) be a set of ground atoms. We say that \( p[I \rightarrow J] \) holds over \( M \) if for all \( p(s_1, \ldots, s_n), p(t_1, \ldots, t_n) \in M \), the following implication holds:

\[
(\forall i \in I. s_i = t_i) \Rightarrow (\forall j \in J. s_j = t_j).
\]

A set \( F \) of functional dependencies holds over \( M \) iff each of them holds over \( M \).

We now show that the set of functional dependencies

\[
F = \{\text{hanoi}[(1, 2, 3, 4) \rightarrow \{5\}], \text{append}[[1, 2] \rightarrow \{3\}]\}
\]

holds over \( \mathcal{A}(\text{HANOI}) \). By the fixpoint definition of \( \mathcal{A}(P) \), if \( A \in \mathcal{A}(P) \), then \( A \) is a ground instance of the head of a clause in \( P \). Then a simple syntactic check on the heads of the clauses in \( \text{HANOI} \) reveals that \( \text{hanoi}[(1, 2, 3, 4) \rightarrow \{5\}] \) holds over \( \mathcal{A}(\text{HANOI}) \). The other functional dependency can be directly established by considering the explicit definition of \( \mathcal{A} \text{(APPEND)} \) previously given.

Using the information given by \( F \) it is now straightforward to prove the implication required by SEM2. The only clause that we have to consider is the nonunit clause for \( \text{hanoi} \). Consider an instance

\[
\begin{align*}
\text{hanoi}(s(n), a, b, c, \text{moves}) &\leftarrow \text{hanoi}(n, a, c, b, \text{ms1}), \text{hanoi}(n, c, b, a, \text{ms2}), \\
&\leftarrow \text{append}(\text{ms1}, [a \text{ to } b | \text{ms2}], \text{moves})
\end{align*}
\]

of such a clause with \( \text{hanoi}(s(n), a, b, c, \text{moves}) \) ground and in \( \mathcal{A}(\text{HANOI}) \).
A CLOSER LOOK AT DECLARATIVE INTERPRETATIONS

Because hanoi([1, 2, 3, 4] → {5}) holds over $\mathcal{M}(\text{HANOI})$, if hanoi(n,a,c,b,msl) $\in \mathcal{M}(\text{HANOI})$, then there exists no hanoi(n,a,c,b,msl') $\in \mathcal{M}(\text{HANOI})$ such that msl $\neq$ msl'. Analogously for ms2 and, using the dependency append [(1, 2) → {3}], for moves. Consequently, SEM2 holds and HANOI is redundancy-free.

A general method for establishing functional dependencies on $\mathcal{M}(P)$, based on an extended version of Armstrong axioms (see Ullman [21]), is given in Maher and Ramakrishnan [16].

Note that Theorem 4.2 only provides sufficient conditions for redundancy-freedom. Indeed, the program $\{p(X) ← q(X,Y), q(a,b), q(a,c)\}$ is easily seen to be redundancy-free, but condition SEM2 does not hold. Moreover, for certain natural programs, Theorem 4.2 cannot be used to establish their subsumption-freedom simply because they are not redundancy-free. An example is, of course, the program considered in Example 4.1, but more natural programs exist. In such situations we still can use a direct reasoning to prove subsumption-freedom.

Example 5.2. Consider the MEMBER program:

$$\text{member}(X, [X\mid Xs]).$$
$$\text{member}(X, [Y\mid Xs]) ← \text{member}(X, Xs).$$

We now prove that MEMBER is subsumption-free. By the $\mathcal{F}$-characterization of Theorem 2.4 it suffices to show that if $I$ is subsumption-free, then $T_{\text{MEMBER}}(I)$ is subsumption-free. Denote the first clause by $c_1$ and the second one by $c_2$. Consider a pair $A_1, A_2 \in T_{\text{MEMBER}}(I)$. The following two cases arise.

Case 1 [$A_1 \in T_{\{=\}}(I)$ and $A_2 \in T_{\{<\}}(I)$]. By definition of $T_{\{\}}$, $A_1 = \text{member}(X, [X\mid Xs])_\rho$ for a renaming $\rho$ and $A_2 = \text{member}(X, [Y\mid Xs])_\theta$, where $\theta$ is an mgu of member(X, Xs) and $B$ for a $B$ such that $Y \not\in \text{Var}(B)$. This implies $X \theta \neq Y \theta$ and hence $A_1 \not\leq A_2$ and $A_2 \not\leq A_1$.

Case 2 [$A_1, A_2 \in T_{\{<\}}(I)$]. By definition, $A_i = \text{member}(X, [Y\mid Xs])_i \theta_i$, where $\theta_i$ is an mgu of member(X, Xs) and $B_i$ for $i = 1, 2$. Assuming $B_i = \text{member}(t_i, 1, _i)$, we have $\theta_i = \{x/t_i, Xs/l_i\}$ (up to renaming). Then the assumption $B_1 \not\leq B_2$ implies $\text{member}(X, Xs) \theta_1 \not\leq \text{member}(X, Xs) \theta_2$ and hence $A_1 \not\leq A_2$. Analogously for the symmetric case.

Note that MEMBER is not redundancy-free. In fact, the query $\text{member}(X, Y)$ has the computed instances $\text{member}(X, [X\mid Xs])$ and $\text{member}(X, [Y\mid Xs])$ which are unifiable.

6. FOURTH SEMANTICS—$\mathcal{M}_{(pre, post)}$

The results of the previous sections indicate that the $\mathcal{M}$-semantics precisely captures the procedural interpretation for the subsumption-free programs. However, it should be noticed that for many programs it is quite cumbersome to construct their least Herbrand model. Note, for example, that $\mathcal{M}(\text{APPEND})$ con-
tains elements of the form \( \text{append}(s, t, u) \), where neither \( t \) nor \( u \) is a list, and analogously for \( \mathcal{A}(\text{MEMBER}) \), because it can be shown that

\[
\mathcal{A}(\text{MEMBER}) = \{ \text{member}(t, [t_1 | t_2 | \cdots | t_n]) \mid n \geq 2, t, t_1, \ldots, t_n \text{ are ground terms and } t = t_j \text{ for some } j \in [1, n - 1] \}.
\]

Clearly, it is quite clumsy to reason about programs when even in such simple cases their semantics is defined in such a laborious way. Preferably, one would rather like to associate with the \texttt{APPEND} program the following, more natural meaning:

\[
\{ \text{append}(s, t, u) \mid s, t, u \text{ are ground lists and } s \ast t = u \} \tag{6.1}
\]

and with the \texttt{MEMBER} program the following meaning:

\[
\{ \text{member}(s, t) \mid t \text{ is a ground list and } s \text{ is an element in } t \}.
\]

To be able to do this we have to find a systematic way of associating with the \texttt{APPEND} program the set (6.1), etc. Note that the set (6.1), when viewed as a Herbrand interpretation, is not a model of \texttt{APPEND}, because the first clause does not hold in it.

The solution proposed here involves the use of types. We use the notion of a well-typed query and clause as in Apt [1] (which, from the semantics point of view, coincides with the method of Bossi and Cocco [6] for proving partial correctness), but follow the equivalent presentation of Ruggieri [17], which is more convenient for our purposes.

**Definition 6.1.** Consider a pair \( \text{pre}, \text{post} \) of Herbrand interpretations.

- A query is called \( (\text{pre}, \text{post}) \)-correct if, for every ground instance \( A_1, \ldots, A_n \) of it, for \( j \in [1, n] \),

\[
A_1, \ldots, A_{j-1} \in \text{post} \Rightarrow A_j \in \text{pre}.
\]

- A clause is called \( (\text{pre}, \text{post}) \)-correct if, for every ground instance \( H \leftarrow B_1, \ldots, B_n \) of it,

\[
H \in \text{pre} \land B_1, \ldots, B_{j-1} \in \text{post} \Rightarrow B_j \in \text{pre}, \text{ for } j \in [1, n],
\]

\[
H \in \text{pre} \land B_1, \ldots, B_n \in \text{post} \Rightarrow H \in \text{post}.
\]

- A program is called \( (\text{pre}, \text{post}) \)-correct if every clause of it is.

Note that every instance and every prefix of a \( (\text{pre}, \text{post}) \)-correct query is \( (\text{pre}, \text{post}) \)-correct.

Given a pair of Herbrand interpretations \( \text{pre}, \text{post} \), correct program \( P \), we now define its “well-typed” semantics as

\[
\mathcal{M}(\text{pre}, \text{post})(P) = \mathcal{M}(P) \cap \text{pre}.
\]

Intuitively, \( \mathcal{M}(\text{pre}, \text{post})(P) \) is the “well-typed” fragment of the least Herbrand model of a program \( P \). We call it \( \mathcal{M}(\text{pre}, \text{post}) \)-semantics. Note that the \( \mathcal{M}(\text{pre}, \text{post}) \)-semantics does not depend on \( \text{post} \), but as the following result of Ruggieri [17]
A CLOSER LOOK AT DECLARATIVE INTERPRETATIONS

shows, for (pre, post)-correct programs \( \mathcal{M}_{(pre, post)}(P) \) can be equivalently defined as \( \mathcal{M}(P) \cap \text{pre} \cap \text{post} \).

Lemma 6.1. For a (pre, post)-correct program \( P \) we have \( \mathcal{M}_{(pre, post)}(P) \subseteq \text{post} \).

In general, the \( \mathcal{M}_{(pre, post)} \)-semantics is not a model of the program, but for the (pre, post)-correct queries it turns out to be equivalent to the \( \mathcal{M} \)-semantics. This is the content of the following result.

Lemma 6.2. For a (pre, post)-correct program \( P \) and a (pre, post)-correct query \( Q \),

\[
\mathcal{M}(P) \models Q \iff \mathcal{M}_{(pre, post)}(P) \models Q.
\]

PROOF. \((\Rightarrow)\) Consider a ground instance \( A_1, \ldots, A_n \) of the query \( Q \) such that \( A_1, \ldots, A_n \in \mathcal{M}(P) \). We show, by induction on \( n \), that \( A_j \in \text{pre} \) for \( j \in [1, n] \). For the base case \( (n = 0) \), the claim holds vacuously. For the induction step \( (n > 0) \), we have \( A_1, \ldots, A_{n-1} \in \text{pre} \) by the induction hypothesis. Together with the assumption \( A_1, \ldots, A_{n-1} \in \mathcal{M}(P) \) this implies \( A_1, \ldots, A_{n-1} \in \text{post} \) by Lemma 6.1. By the fact that \( A_1, \ldots, A_n \) is (pre,post)-correct, we conclude that \( A_n \in \text{pre} \), which completes the proof of the first implication.

\((\Leftarrow)\) Obvious, as by definition \( \mathcal{M}_{(pre, post)}(P) \subseteq \mathcal{M}(P) \). [\( \square \)]

The following example should clarify the idea behind this approach to types. Here and in other natural cases \( \text{post} \subseteq \text{pre} \). Then by Lemma 6.2 we have \( \mathcal{M}_{(pre, post)}(P) = \mathcal{M}(P) \cap \text{post} \), which makes the \( \mathcal{M}_{(pre, post)} \)-semantics somewhat easier to construct.

Example 6.1. Consider the program APPEND. In general, APPEND is used either to concatenate two lists or to split a list. This use is reflected in the following choice of pre:

\[
\text{pre} = \{ \text{append}(s, t, u) \mid s, t \text{ are ground lists and } u \text{ is a ground term} \} \\
\cup \{ \text{append}(s, t, u) \mid s, t \text{ are ground terms and } u \text{ is a ground list} \}.
\]

Intuitively, pre is the set of all ground instances of the intended one atom queries. It is readily checked that APPEND is (pre,post)-correct, where

\[
\text{post} = \{ \text{append}(s, t, u) \mid s, t, u \text{ are ground lists} \}.
\]

Now, using the previously obtained characterization of \( \mathcal{M}(\text{APPEND}) \), we obtain

\[
\mathcal{M}_{(pre, post)}(\text{APPEND}) = \{ \text{append}(s, t, u) \mid s, t, u \text{ are ground lists and } s \star t = u \}.
\]

Example 6.1 shows how to construct the set \( \mathcal{M}_{(pre, post)}(P) \) by using the least Herbrand model \( \mathcal{M}(P) \). However, as we already noticed, the construction of \( \mathcal{M}(P) \) can be quite cumbersome, so we would prefer to define \( \mathcal{M}_{(pre, post)}(P) \) directly, without constructing \( \mathcal{M}(P) \) first. To this end we introduce the notion of a reduced program w.r.t. a Herbrand interpretation.

Definition 6.2. Consider a program \( P \) and a Herbrand interpretation \( J \). Then the reduced program w.r.t. \( J \), denoted by \( J(P) \), is the (possibly infinite) program
consisting of the ground instances of clauses from $P$, the head of which is in $J$, that is,
$$J(P) = \{ A \leftarrow B \in \text{Ground}(P) \mid A \in J \}.$$ 

As a direct consequence of the definition, observe that
$$T_{J(P)}(I) = T_P(I) \cap J \quad (6.2)$$
and that $T_{J(P)}$ is continuous on the complete lattice of Herbrand interpretations ordered with $\leq$.

We now prove that for a (pre,post)-correct program $P$, the $(\mathcal{M}_{\text{pre,post}})$-semantics coincides with the $\mathcal{M}$-semantics of pre($P$). This result provides us with a method for removing the "ill-typed" atoms from the $\mathcal{M}$-semantics by using the reduced program pre($P$).

**Theorem 6.1.** For a (pre, post)-correct program $P$,
$$\mathcal{M}_{\text{pre,post}}(P) = \mathcal{M}(\text{pre}(P)).$$

**Proof.** By the $\mathcal{M}$-characterization of Theorem 2.1, $\mathcal{M}_{\text{pre,post}}(P) = T_P \uparrow \omega \cap \text{pre}$ and $\mathcal{M}(\text{pre}(P)) = T_{\text{pre}(P)} \uparrow \omega$. Now, on the account of (6.2), we have $T_{J(P)} \uparrow \omega \subseteq T_P \uparrow \omega \cap J$, for all $J$, so for pre in particular. Thus $\mathcal{M}(\text{pre}(P)) \subseteq \mathcal{M}_{\text{pre,post}}(P)$.

To prove the other inclusion we show by induction that, for $n \geq 0$,
$$T_P \uparrow n \cap \text{pre} \subseteq T_{\text{pre}(P)} \uparrow n.$$ 

The induction base ($n = 0$) is obvious. For the induction step ($n > 0$) assume $H \in T_P \uparrow n \cap \text{pre}$. Then there exists a ground instance $H \leftarrow B_1 \ldots B_m$ of a clause in $P$ such that
$$\{B_1 \ldots B_m\} \subseteq T_P \uparrow (n - 1). \quad (6.3)$$

Because the program $P$ is (pre,post)-correct, it is easy to prove by induction on $m$, that also the inclusion
$$\{B_1 \ldots B_m\} \subseteq \text{pre} \quad (6.4)$$
holds. Indeed, for the base case ($m = 0$), the claim holds vacuously. For the induction step ($m > 0$), assume that $\{B_1 \ldots B_{m-1}\} \subseteq \text{pre}$. This together with (6.3) implies $\{B_1 \ldots B_{m-1}\} \subseteq \mathcal{M}_{\text{pre,post}}(P)$ and hence, by Lemma 6.1, $\{B_1 \ldots B_{m-1}\} \subseteq \text{post}$ holds. Because by assumption $H \in \text{pre}$, it follows from Definition 1 that $B_m \in \text{pre}$.

Now the induction hypothesis, (6.3), and (6.4) imply $\{B_1 \ldots B_m\} \subseteq T_{\text{pre}(P)} \uparrow (n - 1)$ and, consequently, $H \in T_{\text{pre}(P)} \uparrow n$, which concludes the proof. $\Box$

This allows us to conclude that the $(\mathcal{M}_{\text{pre,post}})$-semantics admits the characterizations analogous to those of the other three semantics so far considered, namely, we have the following analogue of the characterization Theorems 2.1, 2.2, and 2.4.

**Theorem 6.2 ($\mathcal{M}_{\text{pre,post}}$-characterization 1).** For a (pre,post)-correct program $P$:

(i) $T_{\text{pre}(P)}$ is continuous on the complete lattice of Herbrand interpretations ordered with $\subseteq$.

(ii) $\mathcal{M}_{\text{pre,post}}(P)$ is the least fixpoint and the least pre-fixpoint of $T_{\text{pre}(P)}$.

(iii) $\mathcal{M}_{\text{pre,post}}(P) = T_{\text{pre}(P)} \uparrow \omega$. 

PROOF. We already noticed that (i) is a consequence of (6.2). (ii) and (iii) follow directly from Theorem 6.1 and Theorem 2.1 applied to \( \text{pre}(P) \). □

As already mentioned, in specific applications it is often the case that for a \((\text{pre}, \text{post})\)-correct program, we have \( \text{post} \subseteq \text{pre} \). In this case an alternative characterization of the \( \mathcal{M}_{(\text{pre}, \text{post})} \)-semantics in terms of \( \text{post}(P) \) can be given, namely, we have the following analogue of Theorem 6.2.

**Theorem 6.3** \((\mathcal{M}_{(\text{pre}, \text{post})})\)-characterization 2). Suppose that \( \text{post} \subseteq \text{pre} \). Then, for a \((\text{pre}, \text{post})\)-correct program \( P \):

(i) \( T_{\text{post}}(P) \) is continuous on the complete lattice of Herbrand interpretations ordered with \( \subseteq \).

(ii) \( \mathcal{M}_{(\text{pre}, \text{post})}(P) \) is the least fixpoint and the least pre-fixpoint of \( T_{\text{post}}(P) \).

(iii) \( \mathcal{M}_{(\text{pre}, \text{post})}(P) = T_{\text{post}}(P) \uparrow \omega \).

PROOF. By Lemma 6.1, \( \mathcal{M}_{(\text{pre}, \text{post})}(P) \subseteq \text{post} \). Thus to prove (ii) and (iii) it suffices to prove by the \( \mathcal{M}_{(\text{pre}, \text{post})}\)-characterization 1 of Theorem 6.2 that \( \text{post} \subseteq \text{pre} \) implies that, for \( n \geq 0 \),

\[
T_{\text{pre}}(P) \uparrow n \cap \text{post} = T_{\text{post}}(P) \uparrow n.
\]

The proof of the \( \subseteq \) inclusion does not use the assumption \( \text{post} \subseteq \text{pre} \) and is by induction on \( n \). The induction base (\( n = 0 \)) is obvious. For the induction step (\( n > 0 \)) assume \( H \in T_{\text{pre}}(P) \uparrow n \cap \text{post} \). Then there exists a ground instance \( H \leftarrow B_1 \cdots B_m \) of a clause in \( \text{pre}(P) \) such that

\[
\{B_1, \cdots, B_m\} \subseteq T_{\text{pre}}(P) \uparrow (n-1).
\]

By Lemma 6.1 and the \( \mathcal{M}_{(\text{pre}, \text{post})}\)-characterization 1 of Theorem 6.2, we also have

\[
\{B_1, \cdots, B_m\} \subseteq \text{post},
\]

so by the induction hypothesis \( \{B_1, \cdots, B_m\} \subseteq T_{\text{post}}(P) \uparrow (n-1) \) and, consequently, \( H \in T_{\text{post}}(P) \uparrow n \cap \text{post} \).

For the other inclusion, note that \( T_{\text{post}}(P) \uparrow n \subseteq T_{\text{post}}(P) \uparrow n \cap \text{post} \) and \( \text{post} \subseteq \text{pre} \) now implies \( T_{\text{post}}(P) \uparrow n \cap \text{post} \subseteq T_{\text{pre}}(P) \uparrow n \cap \text{post} \). This concludes the proof. □

Returning to Example 6.1, note that using the above theorem it is now easy to construct \( \mathcal{M}_{(\text{pre}, \text{post})}(\text{APPEND}) \) by proving by induction on \( n > 0 \) that

\[
T_{\text{post}}(\text{APPEND}) \uparrow n = \{ \text{append}(s, t, u) \mid s, t, u \text{ are ground lists,}
\]

\[
s \text{ is of length } n-1 \text{ and } s * t = u \}.
\]

Finally, let us remark that for a large class of programs it is possible to verify that a Herbrand interpretation coincides with the \( \mathcal{M}_{(\text{pre}, \text{post})} \)-semantics in a simple way. Call a program **left terminating** if all its SLD derivations w.r.t. the leftmost selection rule, starting with a ground query, are finite. Call a model \( I \) of a program \( P \) **supported** if for every ground atom \( A \) such that \( I \models A \) there exists \( B \) such that \( A \leftarrow B \in \text{Ground}(P) \) and \( I \models B \).

In Apt and Pedreschi [4] it is argued that most natural pure Prolog programs are left terminating and a natural method is proposed to prove that a program is left terminating. A result of Apt and Pedreschi [4] states that for a left terminating
program $P$ the least Herbrand model $\mathcal{M}(P)$ of $P$ is the unique supported Herbrand model of $P$. Now, if $P$ is left terminating, then so is $\text{Ground}(P)$ and a fortiori $\text{pre}(P)$ and $\text{post}(P)$. Thus, for a left terminating program, by the $\mathcal{M}_{\text{(pre, post)}}(P)$ characterization of Theorems 6.2 and 6.3 we have that $\mathcal{M}_{\text{(pre, post)}}(P)$ is the unique supported Herbrand model of $\text{pre}(P)$ and, if $\text{post} \subseteq \text{pre}$, the unique supported Herbrand model of $\text{post}(P)$. Usually, checking that a given Herbrand interpretation is a supported model is straightforward.

7. APPLICATIONS TO PROGRAM VERIFICATION

When dealing with correctness of logic programs, one needs to prove the following properties for a given program and a "relevant" query:

- All its SLD derivations terminate.
- All successful SLD derivations yield the desired results.
- Absence of failure, that is an existence of a successful SLD derivation.

The first property has been dealt with in numerous papers and is not discussed here. The second property is usually referred to as partial correctness. Partial correctness of logic programs has been studied for a long time (see, for example, Deransart [9], where various approaches are discussed and compared). Among them the most powerful one is the inductive assertion method of Drabent and Mahuszyński [10] that allows us to prove various program properties that can be expressed only using nonmonotonic assertions (like $\text{var}(X)$). Various other, simpler cases of this method were presented in the literature. Apt and Marchiori [3] provided a systematic, comparative study of the relative strength and expressive power of these versions of the inductive assertion method and showed that they can be arranged in a natural hierarchy.

In contrast, we are not familiar with any approaches to prove the third property —absence of failures. In what follows we show how the results of the previous sections can be applied to prove this property together with the proof of partial correctness.

The point of departure in our approach is the observation that logic and pure Prolog programs can yield several answers and, consequently, partial correctness could be interpreted in two ways.

Take as an example the APPEND program. It is natural that for the query $\text{append}([1,2], [3,4], Zs)$ we would like to prove that upon successful termination, the variable $Zs$ is instantiated to $[1,2,3,4]$, that is, that $\{Zs/\ [1,2,3,4]\}$ is the computed answer substitution.

On the other hand, for the query $\text{append}(Xs, Ys, [1,2,3,4])$ we would like to prove that all possible splittings of the list $[1,2,3,4]$ can be produced. This means that for this query we would like to prove that each of the substitutions

$$
\{Xs/\ [\ ], Ys/\ [1, 2, 3, 4]\}, \\
\{Xs/\ [1], Ys/\ [2, 3, 4]\}, \\
\{Xs/\ [1,2], Ys/\ [3,4]\}, \\
\{Xs/\ [1, 2, 3], Ys/\ [4]\}, \\
\{Xs/\ [1, 2, 3, 4], Ys/\ [\ ]\}
$$
is a possible computed answer substitution to the query \( \text{append}(Xs, Ys, [1,2,3,4]) \).

Moreover, we should also prove that no other answer can be produced. This boils down to the claim that the above set of substitutions coincides with the set of all computed answer substitutions. Of course, a similar strengthening is possible in the case of the first query. We would prove that the query \( \text{append}([1,2], [3,4], Zs) \) admits precisely one computed answer substitution, namely, \( \{Zs/ [1,2,3,4]\} \).

Note that such a stronger formulation of partial correctness automatically takes care of the proof of the last property—absence of failure. Indeed, this property reduces to the statement that the set of computed answer substitutions is nonempty. This explains why this formulation of partial correctness is beyond the scope of other methods.

In the terminology introduced in Section 1.2 for a given program \( P \) and a query \( Q \), we thus wish to prove assertions of the form \( \{Q\}P \). In particular, we would like to prove that

\[
\{\text{append}([1,2], [3,4], Zs)\} \text{ APPEND } \{\text{append}([1,2], [3,4], [1,2,3,4])\}
\]

and

\[
\{\text{append}(Xs, Ys, [1,2,3,4])\} \text{ APPEND } \emptyset,
\]

where

\[
Q = \{
\text{append}([], [1,2,3,4], [1,2,3,4]),
\text{append}([1], [2,3,4], [1,2,3,4]),
\text{append}([1,2], [3,4], [1,2,3,4]),
\text{append}([1,2,3], [4], [1,2,3,4]),
\text{append}([1,2,3,4], [], [1,2,3,4])
\}.
\]

In Apt [1] it was shown how these properties can be established using the least Herbrand model. However, this approach was limited only to the case of "ground" inputs (or more precisely, to the queries with only "ground" computed instances). We now show that in the case of subsumption-free programs this approach can be generalized to arbitrary queries.

To this end one should perform the steps listed below. We illustrate this technique by means of an example that shows that this method can also deal with programs that use logical variables. Consider the following program \textsc{reverse\_dl}, which computes the reverse of a list using difference lists:

\[
\text{reverse}(Xs, Ys) \leftarrow \text{reverse\_dl}(Xs, Ys-[\]).
\]

\[
\text{reverse\_dl}([X|Xs], Ys-Zs) \leftarrow \text{reverse\_dl}(Xs, Ys-[X|Zs]).
\]

\[
\text{reverse\_dl}([], Xs-Xs).
\]
Take the query $Q = \text{reverse}(s, X)$, where $s$ is a (possibly nonground) list and $X$ is a variable. In the following, we assume an infinite signature.

1. **Construct $\mathcal{A}(P)$**. Recall from Example 5.1 that for a list $s$, $\text{rev}(s)$ denotes its reverse. Using the $\mathcal{A}$-characterization of Theorem 2.1, one can show that

$$\mathcal{A}(\text{REVERSE\_DL}) = \{\text{reverse\_dl}(s, t-u) \mid s \text{ is a ground list}, \quad t, u \text{ are ground terms and } \text{rev}(s) * u = t\}$$

$$\cup \mathcal{A}(\text{reverse}(s, t) \mid s, t \text{ are ground lists and } t = \text{rev}(s))$$

2. **Prove that $P$ is redundancy or subsumption-free**. In the case of $\text{REVERSE\_DL}$ it suffices to note that it satisfies the conditions SYN1 and SYN2 and apply Theorem 4.2.

3. **Find a correct instance $Q'$ of $Q$**, i.e., such that $\mathcal{A}(P) \models Q'$. Note that by definition

$$\mathcal{A}(P) \models Q' \iff \text{Ground}(Q') \subseteq \mathcal{A}(P)^*.$$ 

(7.1)

In our case, by the form of $\mathcal{A}(\text{REVERSE\_DL})$, if $Q''$ is a ground instance of $\text{reverse}(s, \text{rev}(s))$, then $Q'' \in \mathcal{A}(\text{REVERSE\_DL})$ holds. Therefore, by (7.1),

$$\mathcal{A}(\text{REVERSE\_DL}) \models \text{reverse}(s, \text{rev}(s)).$$

4. **By suitably generalizing from (3), find a minimal correct instance $Q'$ of $Q$**, i.e., such that $\mathcal{A}(P) \models Q'$ implies $Q' \preceq Q\gamma$. (In general, find the set of minimal correct instances of $Q$.) Here the following implication, which holds for any pair of expressions $E_1, E_2$, can be useful:

$$(\forall \eta. (E_1 = E_2) \eta \text{ is ground } \Rightarrow E_1\eta = E_2\eta) \Rightarrow E_1 = E_2.$$ 

(7.2)

In our case, assume that

$$\mathcal{A}(\text{REVERSE\_DL}) \models \text{reverse}(s, X)\gamma.$$ 

We have $X\gamma\eta = \text{rev}(s)\gamma\eta = (by \text{definition of } \text{rev}) \text{rev}(s)\gamma\eta$. Then, by (7.2), $X\gamma = \text{rev}(s)\gamma$ and hence

$$\text{reverse}(s, \text{rev}(s)) \preceq \text{reverse}(s, X)\gamma$$

holds.

5. **Apply Corollary 4.1 (or Corollary 3.1 for programs that are not redundancy-free)**. For $\text{REVERSE\_DL}$ we obtain

$$\{\text{reverse}(s, X)\} \bowtie \text{REVERSE\_DL Variant}((\text{reverse}(s, \text{rev}(s)))).$$

In view of our comments in Section 6, the drawback of this approach to proving partial correctness is point (1), so the construction of the $\mathcal{A}$-semantics. We also argued that for $\text{pre, post}$-correct programs it is usually easier to construct their $\mathcal{A}_{\text{pre, post}}$-semantics. Therefore, it is legitimate to rephrase the above methodology for partial correctness by using $\mathcal{A}_{\text{pre, post}}(P)$ instead of $\mathcal{A}(P)$. To this end, we introduce the following notion of $(\text{pre, post})$-redundancy-freedom.

**Definition 7.1.** A program $P$ is said to be $(\text{pre, post})$-redundancy-free if it is $(\text{pre, post})$-correct and, for any $(\text{pre, post})$-correct query $Q$, $\text{Min}(\text{sp}(Q, P)) = \text{sp}(Q, P)$, that is, the set of computed instances of $Q$ is subsumption-free.
Observe that, because of Theorem 4.1(ii), for a (pre, post)-correct program $P$, if $P$ is redundancy-free, then it is (pre, post)-redundancy-free. Later we shall exhibit Herbrand interpretations $pre, post$ and a natural program that is (pre, post)-redundancy-free, but not redundancy-free. The next result is a relativized version of Corollary 4.1. It shows that, for (pre, post)-redundancy-free programs, the computed instances of the (pre, post)-correct queries can be retrieved from $\mathcal{M}_{(pre,post)}(P)$, thus motivating the previous definition.

**Corollary 7.1.** Consider a (pre, post)-redundancy-free program $P$ and a (pre, post)-correct query $Q$. Then

$$\begin{align*}
(0) &\quad P \text{ Min}(\{Q \theta | P \models Q \theta\}). \\
(ii) &\quad \{Q\}P \text{ Min}(\{Q \theta | \mathcal{M}(P) \models Q \theta\}). \\
(iii) &\quad \text{If the signature contains infinitely many constant symbols,} \\
&\quad \{Q\}P \text{ Min}(\{Q \theta | \mathcal{M}(P) \models Q \theta\}).
\end{align*}$$

**Proof.** From Claims 1 and 2 of the proof of Corollary 4.1 we obtain (i), (ii), and also

$$\{Q\}P \text{ Min}(\{Q \theta | \mathcal{M}(P) \models Q \theta\}),$$

provided that the signature contains infinitely many constant symbols. Then (iii) follows from Lemma 6.2. 

Thus for (pre, post)-redundancy-free programs, the set of computed instances of a (pre, post)-correct query coincides with the set of its most general instances that are true in $\mathcal{M}(P)$. We are now faced with the problem of proving that a (pre, post)-correct program $P$ is (pre, post)-redundancy-free. Clearly, redundancy freedom is a sufficient condition for (pre, post)-redundancy-freedom. However, the proof method for redundancy freedom, namely, Theorem 4.2, is based on $\mathcal{M}(P)$, whereas for (pre, post)-correct programs, we would like to use $\mathcal{M}_{(pre,post)}(P)$.

To solve this problem, we provide an analogue of Theorem 4.2 that employs a modification of the conditions SEM1 and SEM2. The new conditions refer to $\mathcal{M}_{(pre,post)}(P)$ instead of $\mathcal{M}(P)$ and allow us to prove that a program is (pre, post)-redundancy-free.

In the proof of Theorem 7.1 we use LD resolution, that is, SLD resolution with the leftmost selection rule, as adopted in Prolog. The following lemma, due to Ruggieri [17], will be needed.

**Lemma 7.1 (Persistence).** Let $P$ and $Q$ be (pre, post)-correct and let $\xi$ be an LD derivation of $P \cup \{Q\}$. Then all resolvents in $\xi$ are (pre, post)-correct.

**Theorem 7.1.** Suppose that the following conditions hold for a (pre, post)-correct program $P$:

**SEM1.** If $H \leftarrow B_1$ and $H \leftarrow B_2$ are ground instances of two different clauses in $P$, then

$$\mathcal{M}_{(pre,post)}(P) \not\models H \land B_1 \land B_2.$$
SEM2. If $H \leftarrow B_1$ and $H \leftarrow B_2$ are distinct ground instances of the same clause in $P$, then

$$\mathcal{M}_{(\text{pre, post})}(P) \not\models H \land B_1 \land B_2.$$ 

Then $P$ is (pre, post)-redundancy-free.

**PROOF.** The proof follows closely that of Theorem 4.2. First, we shall need the following observation.

**Claim 1.** Let $\xi$ be an LD refutation of a (pre, post)-correct query and a (pre, post)-correct program $P$ and let $\theta$ be the composition of the mgu's used in $\xi$. If $H \leftarrow B$ is an input clause used in $\xi$, then

$$\mathcal{M}_{(\text{pre, post})}(P) \models (H \land B) \theta.$$ 

**PROOF.** From Claim 1 of the proof of Theorem 4.2 it follows that $\mathcal{M}(P) \models B \theta$, which implies that also $\mathcal{M}(P) \models H \theta$. Furthermore, both $H$ and $B$ are instances of a prefix of a resolvent in $\xi$, so by the persistence lemma (Lemma 7.1), both $H$ and $B$ are (pre, post)-correct. It suffices now to apply Lemma 6.2.

We now prove the contrapositive. Assume that the program $P$ is not (pre, post)-redundancy-free, that is, there exists a (pre, post)-correct query $Q$ that admits two computed instances $Q'$ and $Q''$ such that $Q' < Q''$. By virtue of the strong completeness of SLD resolution, we can consider then two LD refutations $\xi'$ and $\xi''$ for $Q$ that yield its computed instances $Q'$ and $Q''$. The rest of the proof is from now on the same as that of Theorem 4.2, using Claim 1 above instead of Claim 1 of the proof of Theorem 4.2.

**Example 7.1.** Reconsider the MEMBER program of Example 5.2:

- $\text{member}(X, [X|Xs]).$
- $\text{member}(X, [Y|Xs]) \leftarrow \text{member}(X, Xs).$

We showed that MEMBER is subsumption-free, although it is not redundancy-free. We now prove in a straightforward manner that it is (pre, post)-redundancy-free w.r.t. a class of natural queries. Consider

$$\text{pre} = \text{post} = \{\text{member}(x, t) \mid x \text{ is a ground term and}
\text{t is a ground list of distinct elements}\}.$$ 

It is readily checked that MEMBER is (pre, post)-correct and that

$$\mathcal{M}_{(\text{pre, post})}($$ MEMBER $$) = \{\text{member}(x, t) \mid x \text{ is a ground term,}
\text{t is a ground list of distinct elements, and x is in t}\}.$$ 

Condition SYN2 of Section 4 obviously applies to the MEMBER program. To check condition SEM1 of Theorem 7.1, consider two ground instances with a common head of the two clauses of the program: $\text{member}(x, [x|xs])$ and $\text{member}(x, [x|xs]) \leftarrow \text{member}(x, x)$. If

$$\mathcal{M}_{(\text{pre, post})}(\text{MEMBER}) \not\models \text{member}(x, [x|xs]),$$

then all elements in $xs$ are different from $x$ and, therefore,

$$\mathcal{M}_{(\text{pre, post})}(\text{MEMBER}) \not\models \text{member}(x, x),$$

which implies that SEM1 holds for the MEMBER program. By Theorem 7.1 we have that MEMBER is (pre, post)-redundancy-free. Now Corollary 7.1 can be applied to
any query of the form \texttt{member(s, t)}, where \(t\) is a list of pairwise nonunifiable elements, because such a query is \((\text{pre}, \text{post})\)-correct.

We can now summarize our methodology for proving partial correctness on the basis of \(\mathcal{M}_{\text{(pre, post)}}\) semantics.

1. \textit{Construct pre and post such that the program \(P\) and the query \(Q\) are \((\text{pre}, \text{post})\)-correct.} Intuitively, \(\text{pre}\) is the set of ground instances of the intended atomic queries.

2. \textit{Construct \(\mathcal{M}_{\text{(pre, post)}}(P)\).} Usually, the "specification" of the program limited to its ground queries coincides with \(\mathcal{M}(P)\). As explained at the end of Section 6, the techniques of Apt and Pedreschi [4] are useful for verifying validity of such a guess.

3. \textit{Prove that \(P\) is \((\text{pre}, \text{post})\)-redundancy-free.}

4. \textit{Find a correct instance \(Q'\) of \(Q\), i.e., such that \(\mathcal{M}_{\text{(pre, post)}}(P) \models Q'\).}

5. \textit{By suitably generalizing from (4), find a minimal correct instance \(Q'\) of \(Q\), i.e., such that \(\mathcal{M}(P) \models Q' \implies Q' \leq Q\). (In general, find the set of minimal correct instances of \(Q\).)

6. \textit{Apply Corollary 7.1.}

8. PROGRAMS WITH ARITHMETIC

We now apply the results of the previous sections to an extension of logic programming with arithmetic. Because we wish to apply these results to reason about Prolog programs, we follow here Prolog's approach to arithmetic. We extend the syntax by allowing, in the bodies of the program clauses, the arithmetic comparison operators \(<, \leq, =, \neq, \geq, \text{ and } >\) are the \texttt{is} relation of Prolog. We also assume that, conforming to the status of built-ins, in the original program these arithmetic relations are not used in the heads of the clauses.

To model adequately the semantics and the computation process of programs with arithmetic, we follow here the approach of Kunen [13] and first add to each program infinitely many unit clauses that define the ground instances of the arithmetic relations used.

To this end we use the shorthand \texttt{gae} to denote a ground arithmetic expression. Given a \texttt{gae} \(n\), we denote by \(\text{val}(n)\) its value. For example, \(\text{val}(3+4)\) equals 7. So for \(<\) we add the set of unit clauses

\[
M_{<} = \{ m < n \mid m, n \text{ are gaes and } \text{val}(m) < \text{val}(n) \},
\]

for \(\text{is}\) we add the set

\[
M_{\text{is}} = \{ \text{val}(n) \text{ is } n \mid n \text{ is a gae} \},
\]

and so forth, so, for example, \(7\) is \(3+4 \in M_{\text{is}}\).

Now we can apply the previous results on all four semantics to logic programs with arithmetic. However, to deal with partial correctness of these programs, we have to exercise some care because Prolog uses the leftmost selection rule and, moreover, in the case of programs with arithmetic, run-time errors can arise.

From now on all proof-theoretic notions, such as the computed instance, refer to the LD resolution. We extend the LD resolution by stipulating that an LD
derivation ends in an error when the last selected atom is with an arithmetic relation and either of the following statements holds:

- It is of the form \( p(s, t) \), where \( p \) is a comparison operator and either \( s \) or \( t \) are not gae.
- It is of the form \( s \text{ is } t \) and \( t \) is not a gae.

This together with the extension of the programs by the definitions of the arithmetic relations appropriately models Prolog’s computation process. For example, the query \( X \text{ is } 3+4 \) yields, as desired, the computed answer substitution \( \{x/7\} \) and the query \( X \text{ is } Y \) yields an error.

Now, the previously established results concerning partial correctness (so Corollaries 3.1, 4.1, and 7.1) hold for all queries such that their LD derivations do not end in error. This is a consequence of the fact that by the strong completeness of the SLD resolution the set of computed instances does not depend on the selection rule and that for such queries the stipulated extension of the LD resolution coincides with the LD resolution.

This brings us to the problem of proving absence of errors. This has been taken care of in Apt [1]. To make the paper self-contained, we review this method in the setting of (pre, post)-correct programs. We need the following immediate consequence of Lemma 7.1.

**Lemma 8.1.** Let \( P \) and \( Q \) be (pre, post)-correct and let \( \xi \) be an LD derivation of \( P \cup \{Q\} \). Then \( \text{pre} \models A \) for every atom \( A \) selected in \( \xi \).

**Proof.** The first atom of every (pre, post)-correct query is true in pre. □

To apply it to a program \( P \) and a query \( Q \) that use arithmetic relations, it suffices to find a pair pre, post of Herbrand interpretations such that:

- \( P \) and \( Q \) are (pre, post)-correct.
- For arithmetic comparison operators \( p \), \( \text{pre} \models p(s, t) \) implies \( s, t \) are gae.
- For the is relation, \( \text{pre} \models s \text{ is } t \) implies \( t \) is a gae.

Then the LD derivations of \( P \cup \{Q\} \) do not end in error. The following two examples show an application of this methodology.

**Example 8.1.** Consider the following program \( \text{LENGTH} \):

\[
\text{length([], 0)}.
\]

\[
\text{length([X|Ts], N) ← length(Ts, M), N is M+1}.
\]

Let

\[
\text{pre} = \{ \text{length}(s, t) \mid s, t \text{ are ground} \} \cup \{ s \text{ is } t \mid t \text{ is a gae} \},
\]

\[
\text{post} = \{ \text{length}(s, t) \mid s, t \text{ are ground, } t \text{ is agae} \}
\]

\[
\cup \{ s \text{ is } t \mid s, t \text{ are gae} \}.
\]

It is easy to see that then \( \text{LENGTH} \) and all the queries of the form \( \text{length}(s, t) \) are (pre, post)-correct. Thus for all \( s, t \) the LD derivations of \( \text{LENGTH} \cup \{ \text{length}(s, t) \} \) do not end in error.

Moreover, it is easy to check that the conditions SYN1 and SEM2 of Section 4 apply to the \( \text{LENGTH} \) program, so by Theorem 4.2, \( \text{LENGTH} \) is redundancy-free. So
following the procedure explained in Section 7, we conclude that for a list \( s \) and a variable \( N \),

\[
\{ \text{length}(s, N) \} \quad \text{LENGTH Variant}\{ \text{length}(s, |s|) \}
\]

where \(|s|\) is the length of the list \( s \).

**Example 8.2.** Consider the following program DICTIONARY for retrieving a pair (key, value) in a dictionary organized as a binary search tree (in short, a bst):

\[
\text{lookup}(X, V, \text{tree}((Y, V), L, R)) \leftarrow X = := Y.
\]

\[
\text{lookup}(X, V, \text{tree}((Y, _, L, R)) \leftarrow X < Y, \text{lookup}(X, V, L).
\]

\[
\text{lookup}(X, V, \text{tree}((Y, _, L, R)) \leftarrow X > Y, \text{lookup}(X, V, R).
\]

This program is a simplified version of program 15.9 from Sterling and Shapiro [20]. Here, a bst is represented by either the constant \( \text{void} \), denoting the empty bst, or by the term \( \text{tree}((x, v), l, r) \), where \( x \) is a gae, \( v \) is a term, \( l \) and \( r \) are bst, and \( x \) is greater than the keys occurring in the left subtree and smaller than the keys occurring in the right subtree. The program uses the arithmetic equality built-in \( := \), which, similar to \( > \) and \( < \), etc., evaluates both arguments before comparison.

This program has been designed to be queried with bst in the third argument of lookup. As a result, the construction of \( \mathcal{I}(\text{DICTIONARY}) \) is particularly awkward. Recall that by the soundness and completeness of the SLD resolution, \( \mathcal{I}(\text{DICTIONARY}) \) coincides with the set of successful ground atomic queries. However, a ground query \( \text{lookup}(x, v, t) \) with an unordered binary tree \( t \), can either succeed or not, depending on the distribution of the keys in the tree. Take now

\[
\text{pre} = \text{post}
\]

\[
= \{ \text{lookup}(x, v, b) \mid x \text{ is a gae}, v \text{ is a ground term and } b \text{ is a ground bst}
\]

\[
\cup \{ s := t \mid s, t \text{ are gae} \}
\]

\[
\cup \{ s < t \mid s, t \text{ are gae} \}
\]

\[
\cup \{ s > t \mid s, t \text{ are gae} \}.
\]

It is easy to see that DICTIONARY is then \( (\text{pre, post}) \)-correct, and that on virtue of Theorem 6.2 the following natural interpretation is the well-typed fragment of its least Herbrand model:

\[
\mathcal{I}_{(\text{pre, post})}(\text{DICTIONARY}) = \{ \text{lookup}(x, v, b) \mid x \text{ is a gae, } b \text{ is a ground bst,}
\]

\[
\text{and } (x, v) \text{ is an element in } b \},
\]

\[
\cup M_{=} \cup M_< \cup M_>.
\]

Also, from Lemma 8.1 it follows that, for any gae \( x \), term \( v \) and bst \( b \), the LD derivations of \( \text{DICTIONARY} \cup \{ \text{lookup}(x, v, b) \} \) do not end in error. Conditions SYN2 of Section 4 readily applies to the DICTIONARY program. To check condition SEM1 of Theorem 7.1, it suffices to consider three ground instances of the three clauses of the program with a common head, namely,

\[
\text{lookup}(x, v, \text{tree}((y, v), 1, r)) \leftarrow x := := y.
\]

\[
\text{lookup}(x, v, \text{tree}((y, v), 1, r)) \leftarrow x < y, \text{lookup}(x, v, 1).
\]

\[
\text{lookup}(x, v, \text{tree}((y, v), 1, r)) \leftarrow x > y, \text{lookup}(x, v, r).
\]
and observe that, for any two gae x and y, exactly one among \( x = y \), \( x < y \), and \( x > y \) holds in \( \{\text{pre, post}\}(\text{DICTIONARY}) \). This implies that SEM1 applies to the DICTIONARY program, which is therefore (pre, post)-redundancy-free. As a conclusion, following the procedure explained in Section 7, we have that for a gae x, a variable v, and a bst b,

\[
\{\text{lookup}(v, X, b)\}\text{DICTIONARY\text{Variant}}(\{\text{lookup}(x, v, b) \mid (x, v) \text{ is an element of } b\}).
\]

9. CONCLUSIONS

Table 1 presents a list of example programs from the book of Sterling and Shapiro [20] for which we proved that \( \mathcal{P} \)-semantics and \( \mathcal{M} \)-semantics are isomorphic. For each program it is indicated by what method the result was established. For example, SEM1-SYN2 means that condition SEM1 of Theorem 4.2 and condition SYN2 following it were used. DP stands for a “direct proof.” In all cases, condition SEM2 was established by means of the functional dependency analysis.

To deal with programs that use arithmetic relations, we followed the approach of Section 8 and assumed that each such relation is defined by infinitely many ground unit clauses, which form its true ground instances. Note that such ground unit clauses obviously satisfy the conditions SYN1 and SYN2. It should be noted here that the results of this paper hold for programs with infinitely many clauses provided we modify the assumption “the signature has infinitely many constants” to “the signature has infinitely many constants that do not occur in the program.”

Thus, for many “natural” Prolog programs, the \( \mathcal{P} \)-semantics is isomorphic to the \( \mathcal{M} \)-semantics. For such programs it is possible to reason about their partial correctness using the least Herbrand model only. Moreover, the listed programs are (pre, post)-correct with a natural choice of pre and post, which implies that it is

possible to reason about the computed instances of the "well-typed" queries using the \( (\text{pre}, \text{post}) \)-semantics only. This fact is relevant, because according to our experience, the \( (\text{pre}, \text{post}) \)-semantics usually coincides with the specification of the program, limited to the ground instances of the intended atomic queries and, consequently, is relatively easy to construct.

This provides a strong indication that, for most "natural" Prolog programs, it is possible to fully reconstruct the procedural behavior of a program from its declarative specification, a feature that accounts for the unique nature of logic programming.

We thank both the referees of this paper and of Apt and Gabbrielli [2] for useful comments. The research of the first and the third author was partly supported by the ESPRIT Basic Research Action 6810 (Compulog 2). This work was carried out while the second author was visiting CWI, Amsterdam. The stay was supported by the Italian National Research Council (CNR) and by HCM grant ERBCHBGCT930496 in the context of the EUROFOCS project.
