Observation of Light-by-Light Scattering in Ultraperipheral Pb + Pb Collisions with the ATLAS Detector

G. Aad et al.*
(ATLAS Collaboration)

(Received 11 April 2019; published 31 July 2019)

This Letter describes the observation of the light-by-light scattering process, $\gamma\gamma \rightarrow \gamma\gamma$, in Pb + Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV. The analysis is conducted using a data sample corresponding to an integrated luminosity of 1.73 nb$^{-1}$, collected in November 2018 by the ATLAS experiment at the LHC. Light-by-light scattering candidates are selected in events with two photons produced exclusively, each with transverse energy $E_T > 3$ GeV and pseudorapidity $|\eta_\gamma| < 2.4$, diphoton invariant mass above 6 GeV, and small diphoton transverse momentum and acoplanarity. After applying all selection criteria, 59 candidate events are observed for a background expectation of 12 ± 3 events. The observed excess of events over the expected background has a significance of 8.2 standard deviations. The measured fiducial cross section is $78 \pm 13$(stat) ± 7(syst) ± 3(lumi) nb.

DOI: 10.1103/PhysRevLett.123.052001

Light-by-light scattering, $\gamma\gamma \rightarrow \gamma\gamma$, is a quantum-mechanical process that is forbidden in the classical theory of electrodynamics [1,2]. In the standard model (SM), the $\gamma\gamma \rightarrow \gamma\gamma$ reaction proceeds at one-loop level at order $\alpha^4_{\text{EM}}$ (where $\alpha_{\text{EM}}$ is the fine-structure constant) via virtual box diagrams involving electrically charged fermions (leptons and quarks) or $W^\pm$ bosons. However, in various extensions of the SM, extra contributions are possible, making the measurement of $\gamma\gamma \rightarrow \gamma\gamma$ scattering sensitive to new physics. Relevant examples are magnetic monopoles [3], vectorlike fermions [4], and axionlike particles [5,6]. The light-by-light cross section is also sensitive to the effect of possible non-SM operators in an effective field theory [7–9]. Light-by-light scattering graphs with electron loops also contribute to the anomalous magnetic moment of the electron and muon [10,11].

Strong evidence for this process in relativistic heavy-ion (Pb + Pb) collisions at the Large Hadron Collider (LHC) has been reported by the ATLAS [12] and CMS [13] collaborations with observed significances of 4.4 and 4.1 standard deviations, respectively. Exclusive light-by-light scattering can occur in these collisions at impact parameters larger than about twice the radius of the ions, as demonstrated for the first time in Ref. [14]. The strong interaction becomes less significant and the electromagnetic (EM) interaction becomes more important in these ultraperipheral collision (UPC) events. In general, this allows us to study processes involving nuclear photoexcitation, photoproduction of hadrons, and two-photon interactions [15,16]. The EM fields produced by the colliding Pb nuclei can be described as a beam of quasi-real photons with a small virtuality of $Q^2 < 1/R^2$, where $R$ is the radius of the charge distribution, and so, $Q^2 < 10^{-3}$ GeV$^2$ [17,18]. The cross section for the elastic reaction Pb + Pb($\gamma\gamma$) → Pb + Pb$\gamma\gamma$ can then be calculated by convolving the appropriate photon flux with the elementary cross section for the process $\gamma\gamma \rightarrow \gamma\gamma$. Since the photon flux associated with each nucleus scales with the square of the number of protons, the cross section is strongly enhanced relative to proton-proton ($pp$) collisions.

The $\gamma\gamma \rightarrow \gamma\gamma$ reaction has also been measured in photon scattering in the Coulomb field of a nucleus (Delbrück scattering) [19–22] and in the photon-splitting process [23]. A related process, in which initial photons fuse to form a pseudoscalar meson that subsequently decays into a pair of photons, has been studied at electron-positron colliders [24–27].

The previous ATLAS and CMS measurements were based on the Pb + Pb dataset of 0.4 nb$^{-1}$ recorded in 2015 at a nucleon-nucleon (NN) center-of-mass energy of $\sqrt{s_{NN}} = 5.02$ TeV [12,13]. The present Letter describes a new measurement exploiting 1.73 nb$^{-1}$ of Pb + Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV, recorded in November 2018 with the ATLAS detector at the LHC. The analysis follows the approach originally proposed in Ref. [14], which was the basis of the initial ATLAS measurement.

The ATLAS detector [28] is a multipurpose particle detector that covers nearly the entire solid angle around the interaction point (IP) [29]. It consists of an inner detector...
the SUPERCHIC 3.0 Monte Carlo (MC) generator [32]. This exclusive production of two photons, \( \text{Pb} + \text{Pb} (\gamma \gamma) \rightarrow \text{Pb}^{(*)} + \text{Pb}^{(*)} \gamma \gamma \), where the diphoton final state is measured in the central detector, and the incoming Pb ions survive the EM interaction, with a possible EM excitation [30], denoted by (\(	ext{*}\)). Hence, the final state consists of two low-energy photons and no further activity in the detector and, in particular, no reconstructed charged-particle tracks originating from the IP.

A two-level trigger system was used to select events online [31]. It consists of a level-1 trigger implemented using a combination of custom electronics and programmable logic, and a software-based high-level trigger (HLT). Candidate diphoton events were recorded using a dedicated trigger for events with moderate activity in the calorimeter but little additional activity in the detector. At level 1, a logical OR of two conditions was required: at least one EM cluster with \( E_T > 1 \text{ GeV} \) in coincidence with a total \( E_T \) of \( 4–200 \text{ GeV} \) measured in the calorimeter, or at least two EM clusters with \( E_T > 1 \text{ GeV} \) with total \( E_T \) measured in the calorimeter below \( 50 \text{ GeV} \). The upper bound on the total \( E_T \) was optimized to be fully efficient for signal events while allowing the rejection of events from nonperipheral Pb + Pb collisions. At the HLT, the total FCAL \( E_T \) on each side of the IP was required to be consistent with noise (FCAL veto), and the number of hits in the pixel detector (part of the ID) was required to be at most 15.

Simulated \( \gamma \gamma \rightarrow \gamma \gamma \) signal events were generated using the SUPERCHIC 3.0 Monte Carlo (MC) generator [32]. This program takes into account box diagrams with charged leptons, quarks, and \( W^\pm \) bosons. An alternative signal sample was generated using calculations from Ref. [33]. These calculations were then folded with the Pb + Pb photon flux taken from the STARLIGHT 2.0 MC generator [34]. The theoretical uncertainty of the cross section is mainly due to the limited knowledge of the nuclear form factors and initial photon fluxes. This is extensively studied in Refs. [13,35], and the relevant uncertainty is estimated to be 10% within the fiducial phase space of the measurement. Higher-order corrections, which are not included in the calculations, are also part of the theoretical uncertainty and amount to 1%–3% in the fiducial phase space [36,37].

The exclusive diphoton final state can also be produced via the strong interaction through a quark loop in the exchange of two gluons in a color-singlet state. This central exclusive production (CEP) process, \( gg \rightarrow \gamma \gamma \), was also modeled using SUPERCHIC 3.0. This process has a large theoretical uncertainty, of \( \mathcal{O}(100\%) \) [38]; hence the absolute normalization of this background is determined using a control region in the data, as explained later. The \( \gamma \gamma \rightarrow e^+e^- \) process is a potential background when both leptons are reconstructed as photons but is also used for calibration studies in the analysis. The process was modeled with the STARLIGHT 2.0 generator. Its production cross section is computed by combining the Pb + Pb photon flux with the leading-order formula for \( \gamma \gamma \rightarrow e^+e^- \). Two-photon production of quark-antiquark pairs, with their subsequent decay into multiple hadrons, was modeled using HERWIG++ 2.7.1 [39], where the initial photon fluxes from \( pp \) collisions are implemented. The sample was then normalized to cover the differences in the photon fluxes between Pb + Pb and \( pp \) collisions. All simulated events make use of a detector simulation [40] based on GEANT4 [41] and are reconstructed with the standard ATLAS reconstruction software.

Photons are reconstructed from EM clusters in the calorimeter [42] and tracking information provided by the ID, which allows us to identify photon conversions [43]. An energy calibration specifically optimized for photons [44] is applied to account for energy loss before the calorimeter and both lateral and longitudinal shower leakage. Photons in MC samples are corrected [43] for known mismodeling of quantities that describe the properties (“shapes”) of the associated EM showers.

The photon particle identification (PID) in this analysis is based on a selection of these shower-shape variables, optimized for the signal events. Only photons with \( E_T > 3 \text{ GeV} \) and \( |\eta| < 2.37 \), excluding the calorimeter transition region \( 1.37 < |\eta| < 1.52 \), are considered. This allows for good separation between prompt photons and fake signatures due to calorimeter noise, cosmic-ray muons, or nonprompt photons originating from the decay of neutral hadrons. The photon PID is based on a neural network trained on background photons extracted from data and on photons from the signal MC sample. The selection of background photons follows the procedure established in Ref. [12].

Selected events are required to have exactly two photons satisfying the above selection criteria, with a diphoton invariant mass \( (m_{\gamma\gamma}) \) greater than 6 GeV. In order to suppress the \( \gamma \gamma \rightarrow e^+e^- \) background, events are rejected if they have a charged-particle track with \( p_T > 100 \text{ MeV} \), \( |\eta| < 2.5 \), and at least six hits in the pixel and microstrip detectors, including at least one pixel hit. To further suppress \( \gamma \gamma \rightarrow e^+e^- \) events with poorly reconstructed charged-particle tracks, candidate events are required to have no “pixel tracks” matched to a photon candidate with \( |\Delta\eta| < 0.5 \). Pixel tracks are reconstructed using information from the pixel detector only. They are required to have \( p_T > 50 \text{ MeV} \), \( |\eta| < 2.5 \), and at least three hits in the pixel detector. According to the MC simulation, these requirements reduce the fake photon background from the dielectron final state by a factor of \( 10^4 \), while being 93% efficient for \( \gamma \gamma \rightarrow \gamma \gamma \) signal events.
To reduce other fake-photon backgrounds, such as cosmic-ray muons, the transverse momentum of the diphoton system ($p_{T}^{\gamma\gamma}$) is required to be below 1 GeV for $m_{\gamma\gamma} < 12$ GeV and below 2 GeV for $m_{\gamma\gamma} > 12$ GeV. To reduce prompt-photon background from CEP $gg \rightarrow \gamma\gamma$ reactions, an additional requirement on the reduced acoplanarity, $A_{\phi} = (1 - |\Delta\phi_{\gamma\gamma}|/\pi) < 0.01$, is used, which is expected to have $(86 \pm 1)\%$ selection efficiency for the signal. This efficiency is estimated using simulated signal events, and the uncertainty is due to modeling of the photon angular resolution in simulation. The above requirements define the fiducial region for the signal measurement.

Exclusive dielectron pairs from the reaction Pb + Pb($\gamma\gamma$) → Pb($e^+e^-+\pi^0$) are used for various aspects of the analysis, in particular, to validate the EM calorimeter energy scale and resolution [44]. To select $\gamma\gamma \rightarrow e^+e^-$ candidates, events are required to pass the same trigger as for the diphoton selection. Each electron is reconstructed from an EM energy cluster in the calorimeter matched to a track in the ID [45]. The $\gamma\gamma \rightarrow e^+e^-$ events are selected by requiring exactly two oppositely charged electrons, no further charged-particle tracks coming from the interaction region, and dielectron reduced acoplanarity, $A_\phi < 0.01$. The observed $\gamma\gamma \rightarrow e^+e^-$ event yield in data is compatible with that expected from simulation.

The level-1 trigger efficiency is estimated with $\gamma\gamma \rightarrow e^+e^-$ events passing an independent trigger. The level-1 trigger efficiency as a function of the electron EM cluster transverse energy sum, $E_{T}^{cluster1} + E_{T}^{cluster2}$, reaches 60% at 5 GeV and 75% at 6 GeV, with the fully efficient plateau reached at around 10 GeV, as shown in Fig. 1(a). The measured efficiency is parametrized and used to correct the trigger response in the simulation. To test the stability of the results, the analysis is repeated using tighter or looser dielectron event selection criteria, and the resulting differences are taken as a systematic uncertainty. The FCAL veto efficiency is estimated using $\gamma\gamma \rightarrow e^+e^-$ events selected with a dedicated control trigger without involving the FCAL requirement. It is estimated to be $(99.1 \pm 0.6)\%$.

Because of the high hit-reconstruction efficiency and relatively low conversion probability of signal photons in the pixel detector, the inefficiency of the pixel veto requirement at the trigger level is found to be negligible.

The photon reconstruction efficiency is extracted from data using $\gamma\gamma \rightarrow e^+e^-$ events, where one of the electrons emits a hard bremsstrahlung photon due to interaction with the material of the detector. The analysis is performed for events with exactly one identified electron and exactly two reconstructed charged-particle tracks, and a tag-and-probe method is used as described in Ref. [12]. The resulting photon reconstruction efficiency is shown in Fig. 1(b). It rises from about 60% at $E_T = 2.5$ GeV to 90% at $E_T = 6$ GeV and is used to derive simulation-to-data correction factors.

High-$p_T$ exclusive dilepton production ($\gamma\gamma \rightarrow \ell^+\ell^-$, where $\ell = e, \mu$) with final-state radiation (FSR) is used to measure the photon PID efficiency, defined as the probability for a reconstructed photon to satisfy the identification criteria. Events with exactly two oppositely charged tracks with $p_T > 0.5$ GeV are selected from UPC triggered events. In addition, a requirement to reconstruct a photon candidate with $E_T > 2.5$ GeV and $|\eta| < 1.37$ or $1.52 < |\eta| < 2.37$ is imposed. A photon candidate is required to be separated from each track by fulfilling $\Delta R > 0.3$ [29] to avoid leakage between the photon and the electron clusters. The FSR event candidates are required to have $p_T^{\ell\ell} < 1$ GeV requirement, where $p_T^{\ell\ell}$ is the transverse momentum of the three-body system consisting of the two tracks and the photon candidate. Figure 1(c) shows the photon PID efficiency as a function of reconstructed photon $E_T$, where the measurement from data is compared with the one extracted from the signal MC sample. Based on these studies, MC events are corrected using photon $E_T$-dependent simulation-to-data correction factors. The systematic uncertainty on the photon reconstruction and PID efficiencies is estimated by parametrizing the correction factors as a function of the photon $\eta$ instead of the photon $E_T$. 

FIG. 1. (a) Measured level-1 trigger efficiency as a function of the reconstructed transverse energy in $\gamma\gamma \rightarrow e^+e^-$ events, (b) photon reconstruction efficiency as a function of the photon $E_T$ (approximated with $E_{T,1} = p_{T,1}^{\text{track}}$, where track denotes the track of the second leading electron), and (c) photon particle-identification efficiency as a function of the photon $E_T$. 

052001-3
uncertainty, the where the uncertainty accounts for the CR statistical
same selection as for the signal region, but inverting the
track and two photons with measured in a region with exactly one charged-particle
yield observed in these two CRs is extrapolated to the
requiring one or two associated pixel tracks. The event
exactly two photons passing the signal selection but also
imposed. Good agreement is observed between the nor-
Aφ requirement is dropped and the difference with the nominal
requirement significantly reduces the
mistag uncertainty, and the difference found
between the two CRs.

The Aφ < 0.01 requirement significantly reduces the
CEP gg → γγ background. Its remaining contribution is
evaluated from a control region defined by applying the
same selection as for the signal region, but inverting the Aφ
requirement to Aφ > 0.01 [see Fig. 2(a)], and correcting the
measured event yield for the expected signal and γγ → e+e− contributions. The CEP and γγ → e+e− processes
exhibit a significantly broader Aφ distribution than the
γγ → γγ process. In the CEP process gluons recoil against
the Pb nucleus which then dissociates. The shape of the Aφ
distribution for γγ → e+e− events is mainly due to the
curvature of the trajectory of the electrons in the detector
magnetic field before they emit hard photons in their
interactions with the ID material.

The estimated uncertainty in the CEP gg → γγ background
takes into account the statistical uncertainty of the
number of events in the Aφ > 0.01 control region (17%) as
well as experimental and modeling uncertainties. It is found
that all experimental uncertainties have negligible impact
on the normalization of the CEP gg → γγ background.
The impact of the MC modeling of the Aφ shape is estimated
using an alternative SUPERCHIC MC sample with no
absorptive effects [46]. These effects reflect the absence
of secondary particle emissions, which can take place in
addition to the gg → γγ process. After applying the data-
driven normalization procedure, this leads to a 25% change
in the CEP background yield in the signal region, which is
taken as a systematic uncertainty. An additional check is
done by varying the gluon parton distribution function
(PDF). The differences between the MMHT 2014 [47],
CT14 [48], and NNPDF3.1 [49] PDF sets have negligible
impact on the shape of the CEP diphoton Aφ distribution.

The background due to the CEP process in the signal region
is estimated to be 4 ± 1 events. In addition, the energy
deposition in the ZDC, which is sensitive to dissociation of
Pb nuclei, is studied for events before the Aφ selection
is imposed. Good agreement is observed between the nor-
amalized CEP expectation from MC simulation and the
observed events with a signal corresponding to at least one
neutron in the ZDC.

The background contribution from γγ → q̅q production
is estimated using MC simulation based on HERWIG++ and
is found to be negligible. Exclusive two-meson production
can be a potential source of background for light-by-light
scattering events, mainly due to their similar back-to-back

The two electrons exhibit balanced transverse momentum
with an unbalance, \(|p_T^e - p_T^{-}\), expected to be below
30 MeV. This is much smaller than the EM calorimeter
energy resolution, which, thus, can be measured by the
difference \(E_T^{\text{cluster1}} - E_T^{\text{cluster2}}\). Below 10 GeV electron \(E_T\),
the relative energy resolution is found to be between 8% and
10% and is well reproduced by the MC simulation. The
EM energy scale is validated using the ratio of the electron
cluster \(E_T^{\text{cluster}}\) to the electron track \(p_T^{\text{track}}\).

The \(\gamma\gamma \rightarrow e^+e^-\) process can be a source of fake diphoton
events, since misidentification of electrons as photons can
occur when the electron track is not reconstructed or the
electron emits a hard bremsstrahlung photon. The \(\gamma\gamma \rightarrow e^+e^-\) yield in the signal region is evaluated using a data-
driven method. Two control regions (CRs) are defined with
exactly two photons passing the signal selection but also
requiring one or two associated pixel tracks. The event
yield observed in these two CRs is extrapolated to the
signal region using the probability to miss the electron pixel
track if the electron track is not reconstructed (\(p_{\text{mistag}}^e\)). It is
measured in a region with exactly one charged-particle
track and two photons with \(A_{\phi} < 0.01\). In order to verify
the stability of the \(p_{\text{mistag}}^e\) evaluation method, the \(A_{\phi}\)
requirement is dropped and the difference with the nominal
selection is taken as a systematic uncertainty. This leads to
\(p_{\text{mistag}}^e = (47 ± 9)\%\). The number of \(\gamma\gamma \rightarrow e^+e^-\) events in
the signal region is estimated to be \(7 ± 1\text{(stat)} ± 3\text{(syst)}\),
where the uncertainty accounts for the CR statistical
uncertainty, the \(p_{\text{mistag}}^e\) uncertainty, and the difference found
between the two CRs.
topology. Mesons can fake photons either by their intermediate decay into photons (neutral mesons: \( \pi^0, \eta, \eta' \)) or by misreconstructed charged-particle tracks (charged mesons: for example \( \pi^+, \pi^- \) states). Estimates for such contributions are reported in Refs. [14,50–53] and these contributions are considered to be negligible in the signal region.

The background from other fake diphoton events (mainly those induced by cosmic-ray muons) is estimated using a control region with at least one track reconstructed in the muon system and further studied using the reconstructed photon-cluster time distribution. After imposing the \( p_T^{\gamma\gamma} \) requirements, this background is found to be negligible. Background from the \( \gamma\gamma \rightarrow e^+e^-\gamma\gamma \) reaction is evaluated using the MADGRAPH5_AMC@NLO MC generator [54] and the Pb + Pb photon flux from STARLIGHT. This contribution is estimated to be below 1% of the expected signal and, therefore, has negligible impact on the results. The contribution from bottomonia production (for example, \( \gamma\gamma \rightarrow b\bar{b} \rightarrow \gamma\gamma \) or \( \gamma Pb \rightarrow \gamma \rightarrow \gamma b\bar{b} \rightarrow 3\gamma \)) is calculated using parameters from Refs. [55,56] and considered to be negligible. The contribution from UPC events where both nuclei emit a bremsstrahlung photon is estimated using calculations from Ref. [57]. The cross section for single-bremsstrahlung photon production from a Pb ion in the fiducial region of the measurement is calculated to be below \( 10^{-4} \) pb so that the coincidence of two such occurrences is considered to be negligible.

After applying the signal selection, 59 events are observed in the data where 30 ± 4 (syst) signal events and 12 ± 1 (stat) ± 3(syst) background events are expected. The probability that the data are compatible with the background-only hypothesis was evaluated in a narrower \( 0 < A_\phi < 0.005 \) range which, in studies using simulated data, was found to be most sensitive. In this region, 42 events are observed in the data where \( 25 \pm 3(\text{syst}) \) signal events and \( 6 \pm 1(\text{stat}) \pm 2(\text{syst}) \) background events are expected. The data excess is quantified by calculating the \( \chi^2 \) value using a profile likelihood-ratio test statistic [58], resulting in an observed (expected) statistical significance of 8.2 (6.2) standard deviations.

Photon kinematic distributions for events satisfying all fiducial requirements. It is found to be negligible in the signal region. The activity in the ZDC agrees to be negligible. The contribution from UPC events where both nuclei emit a bremsstrahlung photon is estimated using calculations from Ref. [57]. The cross section for single-bremsstrahlung photon production from a Pb ion in the fiducial region of the measurement is calculated to be below \( 10^{-4} \) pb so that the coincidence of two such occurrences is considered to be negligible.

After applying the signal selection, 59 events are observed in the data where \( 30 \pm 4(\text{syst}) \) signal events and \( 12 \pm 1(\text{stat}) \pm 3(\text{syst}) \) background events are expected. The probability that the data are compatible with the background-only hypothesis was evaluated in a narrower \( 0 < A_\phi < 0.005 \) range which, in studies using simulated data, was found to be most sensitive. In this region, 42 events are observed in the data where \( 25 \pm 3(\text{syst}) \) signal events and \( 6 \pm 1(\text{stat}) \pm 2(\text{syst}) \) background events are expected. The data excess is quantified by calculating the \( \chi^2 \) value using a profile likelihood-ratio test statistic [58], resulting in an observed (expected) statistical significance of 8.2 (6.2) standard deviations. The overall uncertainty is dominated by uncertainties in the photon reconstruction efficiency (4%) and the trigger efficiency (2%). The uncertainty of the integrated luminosity is derived, following a methodology similar to that detailed in Ref. [60], from a calibration of the luminosity scale using \( x-y \) beam-separation scans performed in November 2018.

The measured fiducial cross section is \( 78 \pm 13(\text{stat}) \pm 7(\text{syst}) \pm 3(\text{lumi}) \) nb, which can be compared with the predicted values of \( 45 \pm 5 \) nb from Ref. [14], \( 51 \pm 5 \) nb from Ref. [33], and \( 50 \pm 5 \) nb from SHERARCHIC 3.0 MC simulation [32]. The experiment-to-prediction ratios are \( 1.73 \pm 0.40, 1.53 \pm 0.33, \) and \( 1.56 \pm 0.33, \) respectively.

In summary, this Letter reports the observation of light-by-light scattering in quasireal photon interactions from ultraperipheral Pb + Pb collisions at \( \sqrt{s_{NN}} = 5.02 \) TeV recorded in 2018 by the ATLAS experiment. After applying all selection criteria, 59 data events are observed in the signal region, while 12 ± 3 background events are expected. The dominant background processes, i.e., CEP \( gg \rightarrow \gamma\gamma \rightarrow e^+e^-\gamma\gamma \) as well as other fake-photon backgrounds, are estimated from data. The statistical significance against the background-only hypothesis is found to be 8.2 standard deviations.

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently. We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWFW and FWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC, and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST, and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR, and VSC CR, Czech Republic; DNRF and DNSRC, Denmark; IN2P3-CNRS and CEA-DRF/IRFU, France; SRNSFG, Georgia; BMBF, HGF, and MPG, Germany; GSRT, Greece; RGC, Hong Kong SAR, China; ISF and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRST, Morocco; NWO, Netherlands; RCUK, Norway; MNiSW and NCN, Poland; FCT, Portugal;

The crucial computing support from all WLCG partners is acknowledged gratefully, in particular from CERN, the ATLAS Tier-1 facilities at TRIUMF (Canada), NDGF (Denmark, Norway, Sweden), CC-IN2P3 (France), KIT/GridKA (Germany), INP-CNRS (France), NL-T1 (Netherlands), PIC (Spain), ASGC (Taiwan), RAL (UK) and BNL (USA), the Tier-2 facilities worldwide and large non-WLCG resource providers. Major contributors of computing resources are listed in Ref. [61].

[29] ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the center of the detector and the z axis along the beam pipe. The x axis points from the IP to the center of the LHC ring, and the y axis points upward. Cylindrical coordinates (r, φ) are used in the transverse plane, φ being the azimuthal angle around the z axis. The pseudorapidity is defined in terms of the polar angle θ as η = −ln tan(θ/2). The distance between two objects in η−φ space is ΔR = √(Δη)2 + (Δφ)2. Transverse momentum is defined by pT = p sin θ.

9 Department of Physics, University of Arizona, Tucson, Arizona, USA
10 Department of Physics, University of Texas at Arlington, Arlington, Texas, USA
11 Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan
12 Institut de Física d’Altes Energies (IAFE), Barcelona Institute of Science and Technology, Barcelona, Spain
13 Institute of High Energy Physics, Chinese Academy of Sciences, Beijing, China
14 Physics Department, Tsinghua University, Beijing, China
15 Department of Physics, Nanjing University, Nanjing, China
16 Institute of Physics, University of Belgrade, Belgrade, Serbia
17 Department for Physics and Technology, University of Bergen, Bergen, Norway
18 Physics Division, Lawrence Berkeley National Laboratory and University of California, Berkeley, California, USA
19 Institut für Physik, Humboldt Universität zu Berlin, Berlin, Germany
20 Albert Einstein Center for Fundamental Physics and Laboratory for High Energy Physics, University of Bern, Bern, Switzerland
21 School of Physics and Astronomy, University of Birmingham, Birmingham, United Kingdom
22 Facultad de Ciencias y Centro de Investigaciones, Universidad Antonio Nariño, Bogota, Colombia
23 INFN Bologna and Universita’ di Bologna, Dipartimento di Fisica, Italy
24 INFN Sezione di Bologna, Italy
25 Department of Physics, Boston University, Boston, Massachusetts, USA
26 Department of Physics, Brandeis University, Waltham, Massachusetts, USA
27 Transilvania University of Brasov, Brasov, Romania
28 Horia Hulubei National Institute of Physics and Nuclear Engineering, Bucharest, Romania
29 Department of Physics, Alexandra Ioan Caza University of Iasi, Iasi, Romania
30 National Institute for Research and Development of Isotopic and Molecular Technologies, Physics Department, Cluj-Napoca, Romania
31 University Politehnica Bucharest, Bucharest, Romania
32 West University in Timisoara, Timisoara, Romania
33 Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava, Slovak Republic
34 Department of Subnuclear Physics, Institute of Experimental Physics of the Slovak Academy of Sciences, Kosice, Slovak Republic
35 Physics Department, Brookhaven National Laboratory, Upton, New York, USA
36 Departamento de Física, Universidad de Buenos Aires, Buenos Aires, Argentina
37 California State University, California, USA
38 Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom
39 Department of Physics, University of Cape Town, Cape Town, South Africa
40 Department of Mechanical Engineering Science, University of Johannesburg, Johannesburg, South Africa
41 School of Physics, University of the Witwatersrand, Johannesburg, South Africa
170 Department of Physics and Astronomy, Tufts University, Medford, Massachusetts, USA
171 Department of Physics and Astronomy, University of California Irvine, Irvine, California, USA
172 Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden
173 Department of Physics, University of Illinois, Urbana, Illinois, USA
174 Instituto de Física Corpuscular (IFIC), Centro Mixto Universidad de Valencia—CSIC, Valencia, Spain
175 Department of Physics, University of British Columbia, Vancouver, British Columbia, Canada
176 Department of Physics and Astronomy, University of Victoria, Victoria, British Columbia, Canada
177 Fakultät für Physik und Astronomie, Julius-Maximilians-Universität Würzburg, Würzburg, Germany
178 Department of Physics, University of Warwick, Coventry, United Kingdom
179 Waseda University, Tokyo, Japan
180 Department of Particle Physics, Weizmann Institute of Science, Rehovot, Israel
181 Department of Physics, University of Wisconsin, Madison, Wisconsin, USA
182 Fakultät für Mathematik und Naturwissenschaften, Fachgruppe Physik, Bergische Universität Wuppertal, Wuppertal, Germany
183 Department of Physics, Yale University, New Haven, Connecticut, USA
184 Yerevan Physics Institute, Yerevan, Armenia

*Deceased.
*Also at Department of Physics, King’s College London, London, United Kingdom.
*Also at Istanbul University, Department of Physics, Istanbul, Turkey.
*Also at Instituto de Física Teórica, IFT-UAM/CSIC, Madrid, Spain.
*Also at TRIUMF, Vancouver, British Columbia, Canada.
*Also at Department of Physics and Astronomy, University of Louisville, Louisville, Kentucky, USA.
*Also at Physics Department, An-Najah National University, Nablus, Palestine.
*Also at Department of Physics, California State University, Fresno, USA.
*Also at Department of Physics, University of Fribourg, Fribourg, Switzerland.
*Also at Physics Dept, University of South Africa, Pretoria, South Africa.
*Also at Departament de Física de la Universitat Autonoma de Barcelona, Barcelona, Spain.
*Also at Tomsk State University, Tomsk, and Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia.
*Also at The Collaborative Innovation Center of Quantum Matter (CICQM), Beijing, China.
*Also at Departamento de Física, Instituto Superior Técnico, Universidade de Lisboa, Lisboa, Portugal.
*Also at Università di Napoli Parthenope, Napoli, Italy.
*Also at Institute of Particle Physics (IPP), Canada.
*Also at Department of Physics, University of Adelaide, Adelaide, Australia.
*Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg, Russia.
*Also at Department of Financial and Management Engineering, University of the Aegean, Chios, Greece.
*Also at Centre for High Performance Computing, CSIR Campus, Rosebank, Cape Town, South Africa.
*Also at Department of Physics, California State University, East Bay, USA.
*Also at Institucio Catalana de Recerca i Estudis Avancats, ICREA, Barcelona, Spain.
*Also at Department of Physics, University of Michigan, Ann Arbor, Michigan, USA.
*Also at LAL, Université Paris-Sud, CNRS-IN2P3, Université Paris-Saclay, Orsay, France.
*Also at Graduate School of Science, Osaka University, Osaka, Japan.
*Also at Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Freiburg, Germany.
*a Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan.
*b Also at Institute for Mathematics, Astrophysics and Particle Physics, Radboud University Nijmegen/Nikhef, Nijmegen, Netherlands.
*c Also at Institute of Theoretical Physics, Ilia State University, Tbilisi, Georgia.
d Also at CERN, Geneva, Switzerland.
e Also at Department of Physics, Stanford University, Stanford, California, USA.
f Also at Manhattan College, New York, New York, USA.
g Also at Joint Institute for Nuclear Research, Dubna, Russia.
h Also at Hellenic Open University, Patras, Greece.
i Also at The City College of New York, New York, New York, USA.
j Also at Institute of High Energy Physics, Chinese Academy of Sciences, Beijing, China.
k Also at Department of Physics, California State University, Sacramento, USA.
l Also at Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia.
m Also at Département de Physique Nucléaire et Corpusculaire, Université de Genève, Genève, Switzerland.
n Also at Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom.
o Also at Louisiana Tech University, Ruston, Louisiana, USA.
p Also at School of Physics, Sun Yat-sen University, Guangzhou, China.
q Also at Institute for Nuclear Research and Nuclear Energy (INRNE) of the Bulgarian Academy of Sciences, Sofia, Bulgaria.
