Referred to by ATel #: [3534](#), [3546](#), [3616](#), [3636](#), [7316](#)

We report on recent RXTE, INTEGRAL, and AMI observations of the HMXB Cyg X-1. After having spent 2006 to mid-2010 in an extraordinarily hard state (Nowak et al., 2011, ApJ 728, 13) the source entered a soft state in summer 2010 (ATel #[2711](#), #[2714](#), #[2715](#), #[2721](#), #[2724](#), #[2734](#), #[2751](#), #[2755](#)) which might now be coming to an end. The Swift-BAT hard X-ray flux started to recover, showing an increasing trend starting around 2011-04-18. Similarly the AMI radio flux recovered from being consistent with zero to almost its canonical hard state value of 15 mJy between 2011-04-09 and 2011-04-25. This picture is supported by our recent pointed X-ray observations:

The 20-500 keV INTEGRAL/ISGRI spectrum (66 ks) on 2011-04-11/12 can be described by a power law with a photon index of 2.63 +/- 0.02, consistent with results from our INTEGRAL Key Programme observations throughout the soft state. The 3-40 keV RXTE/PCA spectra (1.4-2.3 ks) can be described by a broken power law with a break at about 10 keV and photon indices PL1 and PL2 below and above the break, respectively, plus a black body component. We also determined rms variability values (for 0.008-256 Hz; narrower than the 0.002-256 Hz of ATel #[2751](#) due to shorter exposure times) and timelags (for 3.2-10 Hz) from 4.5-5.8 keV and 9.5-15 keV PCA lightcurves. Summary of selected parameters (the disk parameters are not well constrained and therefore not included):

obs start [UT]      radio flux [mJy]      photon index PL1      soft band rms [%]      timelag [ms]

nd = no detection					

The decreasing photon index between 2011-04-12 and 2011-04-22 (PL1 and PL2 are correlated; Wilms et al., 2006, A&A 447, 245), the comparatively low rms values, the radio flux turn-on/increase, and especially the enhanced timelag on 2011-04-22 are typical indicators that Cyg X-1 has entered a transitional state. The photon index PL1 on 2011-04-22 is consistent with the one measured for the RXTE monitoring observation on 2010-07-04, classified as transitional in ATel #2751. Abrupt parameter changes within the transitional state have been observed PL1~2.5 before (HIMS-to-SIMS-like transition, Boeck et al., 2011, A&A, in prep.): Cyg X-1 might soon reach this parameter regime.

Even if the source fails to reach the full hard state, this episode can be described as a reverse failed state transition, analogous to the previously observed failed state transitions from the hard to the soft state (Pottschmidt et al, 2003, A&A 407, 1039). Further monitoring of Cyg X-1 will be performed within the RXTE Core Program and within the INTEGRAL Key Programme, as well as with the AMI Large Array. We encourage additional multi-wavelength observations in order to reveal a more detailed view of a soft to hard state transition for a persistent source.
