(Received 26 May 2020; accepted 30 September 2020; published 7 December 2020)

This paper describes a search for beyond the Standard Model decays of the Higgs boson into a pair of new spin-0 particles subsequently decaying into $b\bar{b}$-quark pairs, $H \rightarrow aa \rightarrow (bb)(bb)$, using proton-proton collision data collected by the ATLAS detector at the Large Hadron Collider at center-of-mass energy $\sqrt{s} = 13$ TeV. This search focuses on the range $15 \text{ GeV} \leq m_a \leq 30 \text{ GeV}$, where the decay products are collimated; it is complementary to a previous search in the same final state targeting the range $20 \text{ GeV} \leq m_a \leq 60 \text{ GeV}$, where the decay products are well separated. A novel strategy for the identification of the $a \rightarrow b\bar{b}$ decays is deployed to enhance the efficiency for topologies with small separation angles. The search is performed with 36 fb$^{-1}$ of integrated luminosity collected in 2015 and 2016 and sets upper limits on the production cross section of $H \rightarrow aa \rightarrow (bb)(bb)$, where the Higgs boson is produced in association with a $Z$ boson.

DOI: 10.1103/PhysRevD.102.112006

I. INTRODUCTION

The Higgs boson is a particle with a particularly narrow natural width, and its branching fractions to new light particles can be sizable even if they interact weakly with it. Because of this, several new weakly interacting light particles that would not be visible in inclusive searches can be probed by searching for “beyond the Standard Model” (BSM) Higgs boson decays at the LHC [1]. These new light particles are predicted in several BSM theories with extended Higgs sectors [2–6] that address open questions in high-energy physics. Theories with new light particles weakly coupled to the Higgs boson provide an explanation for electroweak baryogenesis [7,8] and contain fields that mediate interactions between Standard Model (SM) particles and dark matter [9–13]. This paper presents a search for a new spin-0 singlet $a$ that couples to the SM Higgs boson.

When the mass of the spin-0, $m_a$, is less than half of the mass of the Higgs boson, $m_H$, i.e., $2m_a < m_H$, the decay $H \rightarrow aa$ is kinematically allowed. The search in this paper is performed with events in which each $a$ boson decays into a pair of $b$ quarks, and the Higgs boson is produced in association with a $Z$ boson which decays into electrons or muons. The final state with multiple $b$ quarks has the highest branching ratio in several BSM theories when it is kinematically accessible. The $Z$ boson with leptonic decay provides a simple strategy for triggering and selecting events, as well as powerful background rejection. Figure 1 depicts the main production mechanism of the events sought in this paper.

The Higgs boson has been observed by the ATLAS and CMS collaborations [14,15]. A comprehensive program is being pursued to measure its branching ratios to SM particles and to search for decays into exotic or non-SM particles. Current measurements constrain the non-SM branching ratio of the Higgs boson to be less than approximately 21% at 95% confidence level (C.L.) with several assumptions [16], leaving enough room for exotic Higgs boson decays.

ATLAS has previously performed a search where each of the four $b$ quarks was experimentally identified as an individual jet in the detector [17]. The search set upper limits on the production cross section of $ZH$, followed by $H \rightarrow aa \rightarrow (bb)(bb)$, of approximately 0.5 pb at 95% C.L. for $m_a \gtrsim 30 \text{ GeV}$. However, when the mass of the $a$ boson is small, it is produced with large momentum and the jets created in the hadronization of the two $b$ quarks from a single $a \rightarrow b\bar{b}$ decay are reconstructed as a single jet in the calorimeter using the standard ATLAS reconstruction algorithms. Because of this, the previous search that covered the range $20 \text{ GeV} \leq m_a \leq 60 \text{ GeV}$ rapidly loses efficiency for masses $m_a \lesssim 30 \text{ GeV}$.

This article extends the previous analysis in the mass regime $15 \text{ GeV} \leq m_a \leq 30 \text{ GeV}$ by relying on a novel
strategy for the reconstruction and identification of $a \rightarrow b \bar{b}$ decays. The article is structured as follows. Section II describes the relevant features of the ATLAS detector. Section III lists the data collected for this search and details the simulated signal and background event samples that were used to describe the composition of the selected events. Section IV describes the basic reconstruction and identification of leptons and jets using the ATLAS detector. Section V presents the dedicated method for the reconstruction and identification of low-mass $a \rightarrow b \bar{b}$ decays. Section VI explains the strategy for event selection and categorization. Section VII discusses the systematic uncertainties considered in this search, and Sec. VIII presents the results. Finally, Sec. IX presents the conclusion.

II. ATLAS DETECTOR

The ATLAS experiment [18–20] at the LHC is a multipurpose particle detector with a forward-backward symmetric cylindrical geometry and a near $4\pi$ coverage in solid angle.

It consists of an inner tracking detector surrounded by a thin superconducting solenoid providing a 2 T axial magnetic field, electromagnetic and hadron calorimeters, and a muon spectrometer. The inner tracking detector covers the pseudorapidity range $|\eta| < 2.5$. It consists of silicon pixel, silicon microstrip, and transition radiation tracking detectors. Lead/liquid-argon (LAr) sampling calorimeters provide electromagnetic (EM) energy measurements with high granularity. A steel/scintillator-tile sampling calorimeter provides hadronic energy measurements in the central pseudorapidity range ($|\eta| < 1.7$).

![Representative tree-level Feynman diagram for the $ZH$ production processes with the subsequent decays $Z \rightarrow \ell \ell$ ($\ell = e, \mu$) and $H \rightarrow aa \rightarrow (bb)(bb)$.](image)

The end cap and forward regions are instrumented with LAr calorimeters for EM and hadronic energy measurements up to $|\eta| = 4.9$. The muon spectrometer surrounds the calorimeters and is based on three large air-core toroidal superconducting magnets with eight coils each. The field integral of the toroids ranges between 2.0 and 6.0 T m across most of the detector. The muon spectrometer includes a system of precision tracking chambers and fast detectors for triggering. A two-level trigger system is used to select events. The first-level trigger is implemented in custom hardware and uses a subset of the detector information to keep the accepted rate below 100 kHz. This is followed by a software-based trigger that reduces the accepted event rate to 1 kHz on average depending on the data-taking conditions.

III. DATA SET AND SIMULATED EVENT SAMPLES

Events are selected from proton-proton ($pp$) collisions collected by the ATLAS detector at the LHC at $\sqrt{s} = 13$ TeV in 2015 and 2016. Only collisions recorded when all relevant subsystems were operational are considered in the analysis. The data set corresponds to an integrated luminosity of $3.2 \pm 0.1$ fb$^{-1}$ recorded in 2015 and $32.9 \pm 0.7$ fb$^{-1}$ recorded in 2016, for a total of $36.1 \pm 0.8$ fb$^{-1}$ [21]. The uncertainty is obtained from the primary luminosity measurements using the LUCID-2 detector [22]. The data used for this search were collected using the single-electron or single-muon triggers with transverse momentum ($p_T$) thresholds of 20 (26) GeV for muons and 24 (26) GeV for electrons in 2015 (2016) [23].

Simulated event samples are used to study the characteristics of signal events and to calculate the signal efficiency and acceptance, as well as for most aspects of the background estimation. Monte Carlo (MC) samples were produced using the full ATLAS detector simulation [24] based on GeANT4 [25]. To simulate the effects of simultaneous inelastic collisions (pileup), additional interactions were generated using PYTHIA 8.186 [26] with the A2 set of tuned parameters [27] and the MSTW2008LO [28] parton distribution function (PDF) set, and overlaid on the simulated hard-scatter event. Simulated events were reweighted to match the pileup conditions observed in the data. All simulated events are processed through the same reconstruction algorithms and analysis chain as the data. Decays of $b$ and $c$ hadrons were performed by EvGen v1.2.0 [29], except in events simulated with the SHERPA event generator [30].

Signal samples of associated Higgs boson production with a $Z$ boson, $pp \rightarrow ZZ$, were generated with POWHEG-BOX v2 [31–34] using the CT10 PDF set [35] at next-to-leading order (NLO). The sample include gluon-initiated processes at LO. The Higgs boson decay into two spin-0 $a$ bosons and the subsequent decay of each $a$ boson into a pair of $b$ quarks were simulated with PYTHIA 8.186. The $a$-boson decay was performed in the narrow-width approximation and the
coupling to the $b$ quarks is assumed to be that of a pseudoscalar. The information about the parity of the $a$ boson assumed in the simulation is lost in the hadronization of the $b$ quarks and, therefore, the results of this search apply equally to scalars and pseudoscalars. PYTHIA 8.186 was also used for the parton showering, hadronization, and underlying-event simulation with the A14 tune [36]. Signal events were generated for several $a$-boson mass hypotheses: 15, 17.5, 20, 22.5, 25, 27.5, and 30 GeV.

The background samples were generated following exactly the same procedure as described in Ref. [17] and only a summarized description is given here. A sample of top-quark pair events was generated using POWHEG-BOX v2 [37] with the NNPDF3.0NLO PDF set. The parton showers and hadronization were modeled by PYTHIA 8.210 [38] with the A14 tune. To model the $t\bar{t} + b\bar{b}$ background with better precision, the relative contributions of the different heavy-flavor categories in the $t\bar{t}$ sample are scaled to match the predictions of an NLO $t\bar{t} + b\bar{b}$ sample including parton showering and hadronization [39], generated with SHERPA+OPENLOOPS [30,40], using the procedure described in Ref. [41].

The production of $Z$ bosons in association with jets was simulated with SHERPA 2.2.1 [30,42] using the NNPDF3.0NNLO PDF set [43]. The matrix element calculation was performed with COMIX [44] and OPENLOOPS [40] and was matched using the MEPS@NLO prescription [45].

Several subleading backgrounds were also simulated. The diboson + jets samples were generated using SHERPA 2.1.1 [46] and the CT10 PDF set. Associated production of $t\bar{t}W$ and $t\bar{t}Z$ ($t\bar{t}V$) were generated with an NLO matrix element using MadGraph5_aMC@NLO interfaced to PYTHIA 8.210 and the NNPDF3.0NNLO PDF set. Samples of $Wt$ single-top-quark backgrounds were generated using POWHEG-BOX v1 at NLO accuracy using the CT10 PDF set. The production of four top quarks ($t\bar{t}t\bar{t}$) and $t\bar{t}WW$ was simulated with MadGraph5_aMC@NLO at LO accuracy and interfaced to PYTHIA 8.186. Background sources with nonprompt leptons contribute negligibly to this search.

Multijet samples are used to compare the data identification efficiency of the $a \rightarrow b\bar{b}$ decays with simulation. These samples were generated using PYTHIA 8.186, with the LO NNPDF2.3 PDF set and the A14 tune. To increase the number of simulated events with semileptonically decaying hadrons used in this analysis, samples of multijet events filtered to have at least one muon with $p_T > 3$ GeV and $|\eta| < 2.8$ were produced with PYTHIA using the same version, PDF set, and underlying-event tunes as the unfiltered multijet samples. Both the filtered and unfiltered multijet samples produced with PYTHIA were processed through the same ATLAS detector simulation.

### IV. OBJECT RECONSTRUCTION AND SELECTION

This search relies on the efficient reconstruction of electrons and muons in order to identify leptonically decaying $Z$ bosons and the reconstruction of jets to identify $a \rightarrow b\bar{b}$ decays.

Electrons are reconstructed from energy deposited in clusters of cells in the electromagnetic calorimeter matched to tracks in the inner detector [47] and are required to have $p_T > 15$ GeV and $|\eta| < 2.47$. Candidates in the transition region between the barrel and end-cap calorimeters, $1.37 < |\eta| < 1.52$, are excluded. Electrons are identified using the “Tight” criterion based on a likelihood discriminant [48]. Muons are reconstructed by combining matching tracks in the inner detector and the muon spectrometer, and are required to have $p_T > 10$ GeV and $|\eta| < 2.4$. Muon candidates must satisfy the “Medium” identification criterion [49]. An isolation requirement based on the momentum of the tracks and the calorimeter energy around each lepton candidate is imposed to distinguish between leptons coming from the decay of a $Z$ boson and those from nonprompt sources [48,49]. Additionally, all lepton candidates are required to be consistent with the primary vertex, chosen as the reconstructed vertex with the highest sum of the $p_T^2$ of its associated tracks.

Jets are reconstructed from three-dimensional topological energy clusters [50] in the calorimeter using the anti-$k_t$ jet algorithm [51] implemented in the FastJet package [52] with a radius parameter of 0.4. Jets are calibrated using energy- and $\eta$-dependent corrections [53] and are required to have $p_T > 20$ GeV and $|\eta| < 2.5$. Events containing jets arising from noncollision sources or detector noise are removed [54]. Finally, a track-based criterion, the jet vertex tagger (JVT), is used to reduce contributions from jets arising from pileup [55]. In the region $|\eta| < 2.5$, jets are tagged as containing $b$-hadrons using a multivariate discriminant (MV2) score [56]. The MV2 score is obtained from a boosted decision tree (BDT) that combines several algorithms that identify tracks with large impact parameters, secondary vertices, and the topological structure of weak $b$- and $c$-hadron decays inside jets. The BDT was trained using jets reconstructed with the anti-$k_t$ algorithm with a radius parameter $R = 0.4$ from $t\bar{t}$ simulated events to discriminate $b$ jets from $c$ jets and light-flavor jets [57]. In this search, the same BDT is used with a novel strategy described in Sec. VA.

### V. IDENTIFICATION OF LOW-MASS RESONANCES DECAYING INTO $b$-QUARK PAIRS

#### A. Reconstruction and identification of $a \rightarrow b\bar{b}$ decays

For low-mass $a$ bosons, the $b$ quarks from $a$-boson decay tend to have small angular separation $\Delta R$ and can be reconstructed either as a single jet or as multiple jets in the calorimeter depending on their angular separation and the clustering algorithm used. In order to include both cases, all calibrated jets reconstructed using the anti-$k_t$ jet algorithm with radius parameter $R = 0.4$ and $p_T > 20$ GeV are clustered again, using an anti-$k_t$ algorithm with radius parameter $R = 0.8$ [58]. The radius parameter was chosen...
to optimize the signal acceptance in the mass range considered. Each \( R = 0.8 \) jet is considered as a reconstructed \( a \to bb \) candidate. The \( R = 0.8 \) jet will often contain a single anti-\( k_t \) constituent jet with radius parameter \( R = 0.4 \) when the angular separation \( \Delta R \) between the \( b \) quarks from the \( a \to bb \) decay is less than 0.4. The four-momentum of an \( a \to bb \) candidate is the sum of all four-momenta of the set of constituent \( R = 0.4 \) jets. Since the \( R = 0.4 \) constituent jets are calibrated, no additional momentum calibration is necessary.

The hadronization of the two \( b \) quarks which come from an \( a \)-boson decay is identified using variables sensitive to the number of \( b \) hadrons and the mass of the \( a \) boson. The values of these variables are calculated using tracks with \( p_T > 0.4 \) GeV matched to the reconstructed \( a \to bb \) candidate. The matching is performed using the ghost-association method [59], which treats the tracks as four-vectors of infinitesimal magnitude during the jet reconstruction and assigns them to the \( a \to bb \) candidate with which they are clustered. Tracks from the hadronization of different \( b \) quarks are separated by splitting the set of tracks matched to an \( a \to bb \) candidate into multiple track jets. Ideally, the decay of each \( b \) quark should be associated with a different track jet. In this search, the track jets are reconstructed by clustering all matched tracks using an exclusive-\( k_t \) algorithm that produces either two (Ex\( k_t^{(2)} \)) or three (Ex\( k_t^{(3)} \)) final jets [60]. The exclusive-\( k_t \) algorithm implements a sequential clustering in which the two tracks with the smallest \( k_t \) distance, defined as the product of the minimum \( p_T \) of the two tracks and their distance \( \Delta R \), are clustered together if this distance is smaller than the transverse momentum of all tracks. If two tracks are clustered together, their momenta are summed and the two are considered as a single object in the next iteration of the sequential clustering. If the transverse momentum of a track is smaller than all \( k_t \) distances, the track is discarded. Tracks clustered together are considered a final-state track jet. The sequential clustering is interrupted after the step in which all the tracks have been clustered in the desired number of final-state track jets [61]. The splitting into three final jets attempts to capture cases where significant additional radiation is present. The strategy presented here to identify the two \( b \)-quark flight directions as different track jets differs from the method documented in Ref. [62], where the inclusive version of the anti-\( k_t \) algorithm is used. At low \( a \)-boson momenta, the exclusive-\( k_t \) algorithm is able to identify the two \( b \)-quark flight directions in separate track jets more often than the inclusive anti-\( k_t \) algorithm. For a simulated signal event sample with \( m_a = 20 \) GeV, the inclusive anti-\( k_t \) algorithm associates the \( b \)-quark flight directions with different track jets in 46% of cases. In contrast, the flight directions are associated with different exclusive-\( k_t \) track jets in nearly 100% of cases.

The variables used for the \( a \to bb \) identification are calculated using the exclusive-\( k_t \) track jets. For the track jets calculated with the Ex\( k_t^{(2)} \) algorithm, the variables used are the MV2 scores of the two track jets, as well as their angular separation \( \Delta R \) and their \( p_T \) asymmetry, defined as \( (p_T^1 - p_T^2)/(p_T^1 + p_T^2) \). For Ex\( k_t^{(3)} \) track jets, the same variables are used, but they are calculated with the two track jets with highest and lowest MV2 scores among the three track jets. The eight variables are used simultaneously. The MV2 scores identify the presence of a \( b \) hadron in the track jets. Track jets with large \( \Delta R \) separation occur in the decay of a massive state. Track jets with very large \( p_T \) asymmetry can arise from final-state radiation. The variables calculated with Ex\( k_t^{(2)} \) track jets provide most of the discriminating power between signal and background, while the variables calculated in Ex\( k_t^{(3)} \) help disentangle cases where Ex\( k_t^{(2)} \) would fail to identify the flight direction of the \( a \to bb \) decay products.

A BDT is trained with these variables to obtain an efficient identification criterion that distinguishes \( a \to bb \) candidates in signal events that have two \( b \) quarks produced in the decay of a low-mass resonance, from those in top-quark pair events that contain a single \( b \)-quark decay. A sample of simulated SM \( t\bar{t} \) events is used as a source of \( a \to bb \) candidates with a single \( b \)-quark decay, while a simulated signal event sample with \( m_a = 20 \) GeV is used as a source of \( a \to bb \) candidates with two \( b \)-quark decays. The transverse momentum and angular distributions are not included as inputs for the BDT training, but the differences in these distributions among signal and background are partially taken into account since they are correlated with other variables. In order to classify the \( b \)-quark multiplicity of an \( a \to bb \) candidate, \( b \) hadrons in the simulation of the \( b \)-quark hadronization with \( p_T > 5 \) GeV are matched to the candidates using the same ghost-association method as described above. Figure 2 shows the predicted score and efficiency for signal and background events using the trained BDT. The BDT discriminator is also efficient in rejecting events without \( b \) quarks, even if such a sample was not explicitly included in the BDT training. Two event categories based on the BDT score are defined for the analysis using a tight and a loose working point (WP). A high-purity category (HPC) for \( a \to bb \) candidates is selected by requiring a BDT score larger than the tight WP, while a low-purity category (LPC) is selected from candidates with a BDT score between the loose and the tight WPs. The tight WP is defined by a BDT score of 0.3 while the loose WP is defined by a BDT score of 0.1. The tight WP is chosen such that it provides a background rejection 1/100 in order to reduce the backgrounds from \( Z+\) jets and \( tt \) events. The LPC contains a relatively large number of events from processes with zero or one \( b \) quark and is used to select background-enriched samples in the search. Reconstructed \( a \to bb \) candidates in the LPC and HPC are defined as identified \( a \to bb \) candidates and are used in this search. The signal efficiency of the two WPs varies with the mass of the \( a \) boson since mass-dependent variables are used in the training.
The efficiency of the $a \rightarrow b \bar{b}$ identification is measured in data by selecting a multijet sample enriched in gluon decays into $b$ quarks, $g \rightarrow b \bar{b}$. In order to measure the efficiency of the identification criterion for both signal and background, $a \rightarrow b \bar{b}$ candidates are categorized according to the flavor of the track jets that are reconstructed with the Ex$k_t^{(2)}$ algorithm, while the Ex$k_t^{(3)}$ track jets are used exclusively for identification purposes. All $b$ and $c$ hadrons present in the event simulation with $p_T > 5$ GeV are matched to the track jets using the ghost-association method. The track jets are assigned different flavor tags B, C, or L (light flavor) as follows. If a track jet has at least one simulated $b$ hadron matched to it, it is classified as B. If it does not contain a simulated $b$ hadron, but has a simulated $c$ hadron matched to it, it is classified as C. Otherwise it is classified as L. The flavor of an $a \rightarrow b \bar{b}$ candidate is determined by the flavor of the two Ex$k_t^{(2)}$ jets. Most signal $a \rightarrow b \bar{b}$ candidates are BB candidates, while most background candidates are BL candidates. A signal candidate can be classified as BL when the two $b$ quarks decay inside the same track jet or when they have $p_T \leq 5$ GeV. The identification efficiencies for BB and BL $a \rightarrow b \bar{b}$ candidates are measured separately in data for three transverse momentum ranges: $30$ GeV $\leq p_T^{a-bb} < 90$ GeV, $90$ GeV $\leq p_T^{a-bb} < 140$ GeV, and $p_T^{a-bb} \geq 140$ GeV. These three ranges were chosen based on the $p_T^{a-bb}$ spectrum in signal samples and on the number of events in the multijet data sample used for the efficiency measurement. The complete procedure described below is applied independently in each transverse momentum range.

**B. Efficiency measurement of $a \rightarrow b \bar{b}$ identification**

The strategy for the efficiency measurement in data closely follows that used in the measurement of the identification efficiency for boosted 125 GeV Higgs boson decays into a pair of $b$ quarks [62]. A multijet sample is selected from a suite of single-jet triggers that differ by their jet $p_T$ threshold. Only a small fraction of the events identified by the triggers with low $p_T$ threshold are recorded. The choice of which jet events to keep is random and results in an effective integrated luminosity smaller than the total recorded by the ATLAS experiment, but does not introduce any selection bias. The fraction of events kept is known as the trigger prescale fraction. Triggers with a prescale fraction less than one are called prescaled triggers. The lowest jet $p_T$ threshold for which all events are kept is 300 GeV. When comparing events recorded with prescaled and unprescaled triggers, each event is weighted by the inverse of the prescale fraction of the corresponding trigger used to record it.

The $a \rightarrow b \bar{b}$ reconstruction described in Sec. VA is applied to the multijet sample. The events recorded by the multijet triggers are dominated by LL candidates. Since muons are often produced in semileptonic decays of $b$ hadrons, a sample with a larger fraction of BB and BL candidates is selected by requiring exactly one muon matched to one of the Ex$k_t^{(2)}$ track jets. The track jet matched to the muon is called the muon-matched track jet, while the other one is called the non-muon-matched track jet. The selected events are compared with simulated multijet events. In order to account for possible mismodeling of the flavor fractions in simulation relative to those in data, a correction is applied to the simulated event sample. The correction is described in detail in Ref. [62] and only a brief summary is given here. The simulated jet sample is split into subsamples depending on the flavor classification of the $a \rightarrow b \bar{b}$ candidate: BB, BL, CC, CL, and LL. The selected BC fraction in the multijet sample is negligible.
The fraction of each subsample is corrected by fitting the distribution of the signed transverse impact parameter significance \( S_{d0}^{\text{jet}} = d_0 / \sigma(d_0) \) of the two \( E^x_{x}^{(2)} \) track jets to data. The \( S_{d0}^{\text{jet}} \) of a track jet is defined as the average of the three largest signed transverse impact parameter significances \( S_{d0}^{\text{jet}} \) of its constituent tracks, since this observable is used to identify the long lifetime of \( b \) and \( c \) hadrons. The average is used to minimize the impact of misreconstructed tracks on this observable. The track impact parameter \( d_0^{\text{trk}} \) is calculated using the vector from the primary vertex to the point of closest approach of the track. The absolute value of \( d_0^{\text{trk}} \) is the norm of the projection of this vector in the transverse plane, while the sign depends on the angle between this vector and the track jet \( p_T \). If this angle is less than \( \pi/2 \), \( d_0^{\text{trk}} \) is taken as positive. For angles larger than \( \pi/2 \), the track impact parameter is considered negative. Large negative impact parameters are often obtained from interactions with the detector material and not from a long-lived \( b \) - or \( c \)-hadron decay, since the direction of the decay is not correlated with the jet axis.

A total of four flavor correction factors that scale the BB, BL, CC, and CL subsamples are determined from a Poisson likelihood fit of the \( S_{d0}^{\text{jet}} \) distribution to data. A total of four flavor correction factors that scale the BB, BL, CC, and CL subsamples are determined from a Poisson likelihood fit to data. The scale parameter for the LL subsample is determined implicitly by requiring that the total number of candidates in simulation is the same as in data. The covariance matrix of these four parameters is determined from the statistical uncertainties and correlations are interpreted directly building the covariance matrix of the 12 SFs. The statistical uncertainties and correlations are interpreted directly from the likelihood fit to data. The impact of systematic uncertainties in the \( a \rightarrow bb \) identification efficiency between data and simulation. A scale factor (SF) is defined as the ratio of the two efficiencies, \( SF = \varepsilon_{\text{DATA}} / \varepsilon_{\text{MC}} \), for each flavor subsample. Only the BB and BL SFs are measured for both the HPC and LPC. All other flavors are subleading after applying the identification criterion, and for these the efficiency in data is considered the same as in simulation. In order to measure the BB and BL SFs, in both the HPC and LPC, a second Poisson likelihood fit of the \( S_{d0}^{\text{jet}} \) distribution to data is performed after using the identification BDT to select events in both simulation and data. The four SFs measured in each of the three \( p_T^{a \rightarrow bb} \) ranges constitute 12 parameters in total. The complete list of uncertainties is described in Sec. V C. Figure 4 shows the measured efficiencies in both data and simulation, for BB and BL candidates. The bottom panel in the same figure shows the SF as defined above.

C. Systematic uncertainties in the \( a \rightarrow bb \) identification

Several sources of uncertainty are considered when building the covariance matrix of the 12 SFs. The statistical uncertainties and correlations are interpreted directly from the likelihood fit to data. The impact of systematic uncertainties is considered by varying the appropriate quantity in the simulated event samples within \( \pm 1 \sigma \) for each source separately. The impact of each systematic uncertainty is considered by varying the appropriate quantity in the simulated event samples within \( \pm 1 \sigma \) for each source separately.
FIG. 4. Efficiency of the $a \rightarrow bb$ identification criteria measured in data and simulated multijet events. The efficiency is measured in three transverse momentum ranges, separately for (a) BB and (b) BL candidates in both the HPC and LPC. The ratio of the measured values in data and simulation (bottom panels) are SFs used in the analysis when comparing simulation with data. The error bars in the top panels are statistical only, while the hashed bands on the ratios in the bottom panels include the full systematic uncertainties.

FIG. 5. Averaged signed impact parameter significance $S_{\text{jet}}^{\text{det}}$ distributions of the track jet (a) with a muon inside and (b) without a muon, in the $30 \text{ GeV} \leq p_T^{a \rightarrow bb} < 90 \text{ GeV}$ range of $a \rightarrow bb$ candidates in the HPC. The hashed area represents the total uncertainty in the predicted yields.
uncertainty is assessed as the difference in the measured SF when fitting the nominal sample and the one with the corresponding source variation. The covariance matrix from the four flavor-fraction corrections described in Sec. VB is propagated to the SF covariance matrix. The impact of the limited knowledge of the jet energy scale is, once again, considered in the covariance matrix. The uncertainty arising from the choice of hadronization model is included through its effect on the MV2 scores and propagated to the SF covariance matrix. The impact of the limited knowledge of the jet energy scale is, again, considered in the covariance matrix. The chosen value of 50% is based on the level of agreement between the MV2 scores and uncertainty arising from the choice of hadronization model.

Two additional sources of uncertainty are considered. First, there is a possible mismodeling of the efficiency for candidates with flavors other than BB or BL. These components are highly suppressed by the BDT selection. An uncertainty of 50% in the efficiency of other flavor components is propagated to the covariance matrix, with negligible impact. The chosen value of 50% is based on the level of agreement between the MV2 scores and uncertainty arising from the choice of hadronization model.

VI. ANALYSIS STRATEGY

The analysis strategy targets events where a Higgs boson is produced in association with a Z boson. The candidate events are required to be consistent with a ZH event, where the Z boson decays into electrons or muons and the Higgs boson decays into two a bosons each of which decays into a b-quark pair. Events are selected using triggers that require at least one electron or muon. The event is further required to have two oppositely charged electrons or two oppositely charged muons and two reconstructed a → bb candidates. The leading electron or muon is required to have a p_T > 27 GeV and be matched to the lepton candidate reconstructed by the trigger algorithms. The lepton momentum requirement and trigger matching are used so that all events have at least one lepton with p_T above the trigger thresholds. The dilepton mass must be consistent with the categories considered above, which can be interpreted as the ratio between the SF for a particle with mass m_a = 20 GeV and the one for a massless gluon. Only the statistical uncertainties are indicated.
Z-boson mass and is required to be in the range 85 GeV < \( m_{\ell\ell} < 100 \) GeV. Both \( a \to b\bar{b} \) candidates are required to satisfy \( p_T > 30 \) GeV and \( |\eta| < 2.0 \).

Two mass requirements are imposed to select events consistent with a cascade decay \( H \to a a \to (b\bar{b})(b\bar{b}) \). First, the mass difference \( \Delta m^{a-b\bar{b}} = m^{a1} - m^{\bar{b}2} \) between the two \( a \to b\bar{b} \) candidates is required to satisfy \( -25 \text{GeV} < \Delta m^{a-b\bar{b}} < 25 \) GeV. The ordering of \( a \to b\bar{b} \) candidates is based on their transverse momenta, with \( a_1 \) corresponding to the higher-\( p_T \) \( a \to b\bar{b} \) candidate. Second, the mass of the pair of \( a \to b\bar{b} \) candidates is required to be consistent with the Higgs boson mass. The compatibility is assessed with the reduced mass:

\[
m_{\text{red}} = (m^{a1,a2} - m_{H}) - (m^{a1} + m^{\bar{b}2} - m_{a}),
\]

which probes the difference between the invariant mass of the two \( a \to b\bar{b} \) candidates, \( m^{a1,a2} \), and the Higgs boson mass \( m_{H} = 125 \) GeV. It should be noted that \( m_{a} \) is the mass hypothesis for the \( a \) boson.

The reduced mass is required to satisfy \( -40 \text{GeV} < m_{\text{red}} < 20 \) GeV, ensuring that the selection is highly efficient. The presence of \( m_{a} \) in the event selection means that different events are used to search for different mass hypotheses. No conditions on the individual values of \( m^{a1} \) and \( m^{\bar{b}2} \) are imposed. The selected mass window, as a function of mass difference and reduced mass, is shown in Fig. 7 for signal events with \( m_{a} = 20 \) GeV and top-quark pair events.

Two signal-enriched regions are defined for this search. One requires the two reconstructed \( a \to b\bar{b} \) candidates to be identified in the HPC, while the other requires one \( a \to b\bar{b} \) candidate identified in the HPC and one in the LPC. The two main sources of background for this search are top-quark pair and Z-boson events produced in association with additional quarks or gluons. In this search, the normalizations of these two backgrounds are measured in dedicated control regions which are selected to be enriched in the specific background. Three regions dominated by top-quark pair events are selected by requiring the dilepton mass to be outside the Z-boson mass window, i.e., \( m_{\ell\ell} \leq 85 \text{GeV} \) or \( m_{\ell\ell} \geq 100 \text{GeV} \). These three control regions differ by the identification of the two \( a \to b\bar{b} \) candidates, with one requiring both to be in the HPC, a second requiring one \( a \to b\bar{b} \) candidate in the HPC and one in
the LPC and, finally, the third requiring the two $a \to b \bar{b}$ candidates to be identified in the LPC. The three control regions probe $t\bar{t}$ events produced in association with different numbers of heavy-flavor jets. A dedicated control region for Z-boson events is formed by requiring the dilepton mass to be consistent with the Z-boson mass and the two $a \to b \bar{b}$ candidates in the LPC. Figure 8 shows the expected background yield fractions in each of the regions described here.

VII. SYSTEMATIC UNCERTAINTIES

Several sources of systematic uncertainty are considered. The identification efficiency for leptons is measured in Z-boson data events using a tag-and-probe method [47,49]. Small residual disagreements between efficiencies in simulation and those measured in data are corrected as a function of the lepton $p_T$ and $\eta$. The uncertainties in these corrections are propagated through this search. Uncertainties in the lepton momentum scale and resolution are similarly considered.

Uncertainties associated with jets arise from their reconstruction and identification efficiencies. These are due to the uncertainty in the jet energy scale (JES), mass scale, energy resolution and the efficiency of the JVT requirement that is meant to remove jets from pileup. The JES and its uncertainty are derived by combining information from test-beam data, LHC collision data and simulation [53].

The identification efficiency for $a \to b \bar{b}$ candidates in simulation is also corrected by using the SFs measured with the methods described in Sec. V. The full covariance matrix for the 12 SFs is propagated after diagonalization in order to obtain uncorrelated sources of systematic uncertainty. Only $a \to b \bar{b}$ candidates with BB and BL flavors have their identification efficiency corrected in simulation. Candidates with flavors other than BB and BL represent a subleading fraction of candidates selected in this analysis, mostly from BC candidates. In this case, an uncertainty of 50% per candidate is applied, similarly to the uncertainty used when measuring the identification efficiency.

Several sources of systematic uncertainty affecting the modeling of the relative normalization of the background sources in control and signal regions are considered. Since the $Z + \text{jets}$ background normalization is measured in a region with two $a \to b \bar{b}$ candidates in the LPC, where a larger fraction of the candidates do not contain two $b$ quarks, an uncertainty of 50% in the fraction of events which have two or more associated $b$ hadrons is applied. This uncertainty is derived by comparing the level of agreement between data and simulation for $m_{\text{had}} < -40$ GeV calculated with $m_a = 20$ GeV. Similarly, for the top-quark pair background, three uncorrelated relative uncertainties of 50% are assigned to events with one associated $b$ hadron, to events with two or more associated $b$ hadrons, and to events with associated $c$ hadrons. The number of associated hadrons in each event is determined following the procedure described in Ref. [64]. These uncertainties are derived from a comparison of the $t\bar{t} + \text{heavy-flavor}$ production cross sections predicted by POWHEG+PYTHIA and by SHERPA+OPENLOOPS at NLO [64].

Beyond the uncertainties associated with heavy-flavor fractions, several sources of systematic uncertainty affecting the relative normalization between control and signal regions are considered. The procedure closely follows the description in Ref. [17]. For the $t\bar{t}$ background, it includes systematic uncertainties from variations of the factorization and renormalization scales, the PDF set used for simulation, $\alpha_S$, the value of the top-quark mass, the choice of generator, the choice of parton shower and hadronization models, and the effects of initial- and final-state radiation. For the $Z + \text{jets}$ backgrounds, additional relative uncertainties are based on variations of the factorization and renormalization scales and of the parameters used in matching the matrix element to the parton showers in the SHERPA simulation.

Uncertainties in secondary background sources are also considered, affecting their normalization in both the signal and control regions. A 50% normalization uncertainty in the diboson background is assumed [65]. The uncertainties in the $t\bar{t}W$ and $t\bar{t}Z$ NLO cross-section predictions are 13% and 12%, respectively [66,67], and are treated as uncorrelated between the two processes. An additional modeling uncertainty for $t\bar{t}W$ and $t\bar{t}Z$, related to the choice of event generator, parton shower and hadronization models, is derived from comparisons of the nominal samples with alternative ones generated with SHERPA.

Several sources of systematic uncertainty affect the theoretical modeling of the signal. Uncertainties originate from the choice of PDFs, the factorization and renormalization scales, and the parton shower, hadronization and underlying-event models. The combined uncertainty in the expected signal yield from these sources is approximately 8%. Higher-order corrections to the decay of the $a$ boson are small compared to the Higgs boson production uncertainties and, therefore, no additional uncertainty is included.

VIII. RESULTS

The results are obtained from a binned maximum-likelihood fit to the data using the two signal regions and four control regions. The likelihood function is constructed from the product of Poisson probabilities in each region. The parameter of interest (POI) scales the signal $H \to aa \to (b\bar{b})(b\bar{b})$ yield. The overall normalizations of the $Z + \text{jets}$ and $t\bar{t}$ backgrounds are modeled as unconstrained nuisance parameters. Simulation is used to determine the relative yields of $Z + \text{jets}$ and $t\bar{t}$ backgrounds in each signal and control region. Systematic uncertainties described in Sec. VII are incorporated as nuisance parameters with Gaussian priors with a standard deviation equal to the value of the uncertainty, and these nuisance parameters multiply the product of Poisson probabilities. Uncertainties arising from the finite number of simulated
events are modeled using gamma distribution priors [68]. Gamma distributions are used as a generalization of the Poisson distribution since the expected yield predicted in simulated event samples may not be an integer number. Figure 9 and Table I show a comparison of data and simulated event samples may not be an integer number. Poisson distribution since the expected yield predicted in Gamma distributions are used as a generalization of the branching ratio for $ZH$, $H \rightarrow aa \rightarrow (b\bar{b})(bb)$ is calculated before the profile likelihood fit and normalized to the observed limit in the cross section times the expected yield for signal with normalized to the total

and \( t\bar{t} \) backgrounds are fixed to one. For \( m_a = 20 \) GeV, an upper limit of 0.71 pb (0.52\( ^{+0.14}_{-0.31} \) pb) is observed (expected) at 95% C.L. The reduced sensitivity for heavier \( a \)-boson mass hypotheses is due to a lower acceptance caused by the increased separation of the \( b \) jets, while the reduced sensitivity for lighter \( a \)-boson mass hypotheses is due to a lower efficiency to identify the two \( b \) jets inside an \( a \rightarrow b\bar{b} \) candidate. The figure includes the results from a previous analysis targeting the higher range of \( m_a \) [17].

IX. CONCLUSION

A search for Higgs bosons decaying into a pair of new spin-0 particles that subsequently decay into a final state with four \( b \) quarks was presented. The search used 36 fb\(^{-1}\) of 13 TeV proton-proton collision data collected by the ATLAS detector at the LHC. A dedicated strategy for reconstruction and identification of \( a \rightarrow b\bar{b} \) candidates in the mass range 15 GeV \( \leq m_a \leq 30 \) GeV was introduced. The measurement of the acceptance and efficiency of this strategy was described in detail and used to compare data with simulated events in regions with two \( a \rightarrow b\bar{b} \) candidates consistent with the cascade decay \( H \rightarrow aa \rightarrow (b\bar{b})(b\bar{b}) \). The dominant background sources were measured in control regions defined by relaxing some of the identification criteria. No excess of data events consistent with \( H \rightarrow aa \rightarrow (b\bar{b})(b\bar{b}) \) was observed, and upper limits at 95% C.L. on the production cross section \( \sigma_{ZH}B(H \rightarrow aa \rightarrow (b\bar{b})(b\bar{b})) \) were obtained as a function of the \( a \)-boson mass hypothesis. This novel search improves the expected limit on \( \sigma_{ZH}B(H \rightarrow aa \rightarrow (b\bar{b})(b\bar{b})) \) for a mass hypothesis of \( m_a = 20 \) GeV by a factor of 2.5 when compared with the previous ATLAS result which uses the same integrated luminosity.

ACKNOWLEDGMENTS

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.
We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWF and FWF, Austria; ANAS, Azerbaijan; STSC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; ANID, Chile; CAS, MOST and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR and VSC CR, Czech Republic; DNRF and DNSRC, Denmark; IN2P3-CNRS and CEA-DRF/IRFU, France; SRNSFG, Georgia; BMBF, HGF and MPG, Germany; GSRT, Greece; RGC and Hong Kong SAR, China; ISF and Benoziyo Center, Israel; INFN, Italy; MEXT and JSPS, Japan; CNRS/INSU, Morocco; NWO, Netherlands; RCN, Norway; MNiSW and NCN, Poland; FCT, Portugal; MNE/IFA, Romania; MES of Russia and NRC KI, Russia Federation; JINR; MESTD, Serbia; ARRS and MIZŠ, Slovenia; ASTRON, South Africa; MICINN, Spain; SRC and Wallenberg Foundation, Sweden; SERI, SNSF and Cantons of Bern and Geneva, Switzerland; MOST, Taiwan; TAEK, Turkey; STFC, United Kingdom; DOE and NSF, United States of America. SEARCH FOR HIGGS BOSON DECAYS INTO TWO NEW LOW- … PHYS. REV. D 102, 112006 (2020)

51 INFN e Laboratori Nazionali di Frascati, Frascati, Italy
52 Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Freiburg, Germany
53 II. Physikalisches Institut, Georg-August-Universität Göttingen, Göttingen, Germany
54 Département de Physique Nucléaire et Corpusculaire, Université de Genève, Genève, Switzerland
55 Dipartimento di Fisica, Università di Genova, Genova, Italy
56 INFN Sezione di Genova, Italy
57 II. Physikalisches Institut, Justus-Liebig-Universität Giessen, Giessen, Germany
58 SUPA—School of Physics and Astronomy, University of Glasgow, Glasgow, United Kingdom
59 LPSC, Université Grenoble Alpes, CNRS/IN2P3, Grenoble INP, Grenoble, France
60 Laboratory for Particle Physics and Cosmology, Harvard University, Cambridge, Massachusetts, USA
61 Department of Modern Physics and State Key Laboratory of Particle Detection and Electronics, University of Science and Technology of China, Hefei, China
62 Institute of Frontier and Interdisciplinary Science and Key Laboratory of Particle Physics and Particle Irradiation (MOE), Shandong University, Qingdao, China
63 School of Physics and Astronomy, Shanghai Jiao Tong University, KLPPAC-MoE, SKLPPC, Shanghai, China
64 Tsung-Dao Lee Institute, Shanghai, China
65 Kirchhoff-Institut für Physik, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany
66 Physikalisches Institut, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany
67 Faculty of Applied Information Science, Hiroshima Institute of Technology, Hiroshima, Japan
68 Department of Physics, Chinese University of Hong Kong, Shatin, N.T., Hong Kong, China
69 Department of Physics, University of Hong Kong, Hong Kong, China
70 Department of Physics and Institute for Advanced Study, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, China
71 Department of Physics, National Tsing Hua University, Hsinchu, Taiwan
72 JICLab, Université Paris-Saclay, CNRS/IN2P3, 91405, Orsay, France
73 Department of Physics, Indiana University, Bloomington, Indiana, USA
74 INFN Gruppo Collegato di Udine, Sezione di Trieste, Udine, Italy
75 ICTP, Trieste, Italy
76 Dipartimento Politecnico di Ingegneria e Architettura, Università di Udine, Udine, Italy
77 INFN Sezione di Lecce, Italy
78 Dipartimento di Matematica e Fisica, Università del Salento, Lecce, Italy
79 INFN Sezione di Milano, Italy
80 Dipartimento di Fisica, Università di Milano, Milano, Italy
81 INFN Sezione di Napoli, Italy
82 Dipartimento di Fisica, Università di Napoli, Napoli, Italy
83 INFN Sezione di Pavia, Italy
84 Dipartimento di Fisica, Università di Pavia, Pavia, Italy
85 INFN Sezione di Pisa, Italy
86 Dipartimento di Fisica E. Fermi, Università di Pisa, Pisa, Italy
87 INFN Sezione di Roma, Italy
88 Dipartimento di Fisica, Sapienza Università di Roma, Roma, Italy
89 INFN Sezione di Roma Tor Vergata, Italy
90 Dipartimento di Fisica, Università di Roma Tor Vergata, Roma, Italy
91 INFN Sezione di Roma Tre, Italy
92 Dipartimento di Matematica e Fisica, Università Roma Tre, Roma, Italy
93 INFN-IFPA, Italy
94 Università degli Studi di Trento, Trento, Italy
95 Institut für Astro- und Teilchenphysik, Leopold-Franzens-Universität, Innsbruck, Austria
96 University of Iowa, Iowa City, Iowa, USA
97 Department of Physics and Astronomy, Iowa State University, Ames, Iowa, USA
98 Joint Institute for Nuclear Research, Dubna, Russia
99 Departamento de Engenharia Elétrica, Universidade Federal de Juiz de Fora (UFJF), Juiz de Fora, Brazil
100 Universidade Federal do Rio De Janeiro COPPE/EE/IF, Rio de Janeiro, Brazil
101 Universidade Federal de São João del Rei (UFSJ), São João del Rei, Brazil
102 Instituto de Física, Universidade de São Paulo, São Paulo, Brazil
103 KEK, High Energy Accelerator Research Organization, Tsukuba, Japan
104 Graduate School of Science, Kobe University, Kobe, Japan

112006-25
AGH University of Science and Technology, Faculty of Physics and Applied Computer Science, Krakow, Poland

Marian Smoluchowski Institute of Physics, Jagiellonian University, Krakow, Poland

Institute of Nuclear Physics Polish Academy of Sciences, Krakow, Poland

Faculty of Science, Kyoto University, Kyoto, Japan

Kyoto University of Education, Kyoto, Japan

Research Center for Advanced Particle Physics and Department of Physics, Kyushu University, Fukuoka, Japan

Instituto de Física La Plata, Universidad Nacional de La Plata and CONICET, La Plata, Argentina

Physics Department, Lancaster University, Lancaster, United Kingdom

Oliver Lodge Laboratory, University of Liverpool, Liverpool, United Kingdom

Department of Experimental Particle Physics, Jožef Stefan Institute and Department of Physics, University of Ljubljana, Ljubljana, Slovenia

School of Physics and Astronomy, Queen Mary University of London, London, United Kingdom

Department of Physics, Royal Holloway University of London, Egham, United Kingdom

Department of Physics and Astronomy, University College London, London, United Kingdom

Louisiana Tech University, Ruston, Louisiana, USA

Fysiska institutionen, Lunds universitet, Lund, Sweden

Centre de Calcul de l’Institut National de Physique Nucléaire et de Physique des Particules (IN2P3), Villeurbanne, France

Departamento de Física Teorica C-15 and CIAFF, Universidad Autónoma de Madrid, Madrid, Spain

Institut für Physik, Universität Mainz, Mainz, Germany

School of Physics and Astronomy, University of Manchester, Manchester, United Kingdom

CPPM, Aix-Marseille Université, CNRS/IN2P3, Marseille, France

Department of Physics, University of Massachusetts, Amherst, Massachusetts, USA

Department of Physics, McGill University, Montreal QC, Canada

School of Physics, University of Melbourne, Victoria, Australia

Department of Physics, University of Michigan, Ann Arbor, Michigan, USA

Department of Physics and Astronomy, Michigan State University, East Lansing, Michigan, USA

B.I. Stepanov Institute of Physics, National Academy of Sciences of Belarus, Minsk, Belarus

Research Institute for Nuclear Problems of Byelorussian State University, Minsk, Belarus

Group of Particle Physics, University of Montreal, Montreal QC, Canada

P.N. Lebedev Physical Institute of the Russian Academy of Sciences, Moscow, Russia

National Research Nuclear University MEPhI, Moscow, Russia

D.V. Skobeltsyn Institute of Nuclear Physics, M.V. Lomonosov Moscow State University, Moscow, Russia

Fakultät für Physik, Ludwig-Maximilians-Universität München, München, Germany

Max-Planck-Institut für Physik (Werner-Heisenberg-Institut), München, Germany

Nagasaki Institute of Applied Science, Nagasaki, Japan

Graduate School of Science and Kobayashi-Maskawa Institute, Nagoya University, Nagoya, Japan

Department of Physics and Astronomy, University of New Mexico, Albuquerque, New Mexico, USA

Institute for Mathematics, Astrophysics and Particle Physics, Radboud University Nijmegen/Nikhef, Nijmegen, Netherlands

Nikhef National Institute for Subatomic Physics and University of Amsterdam, Amsterdam, Netherlands

Department of Physics, Northern Illinois University, DeKalb, Illinois, USA

Budker Institute of Nuclear Physics and NSU, SB RAS, Novosibirsk, Russia

Novosibirsk State University Novosibirsk, Russia

Institute for High Energy Physics of the National Research Centre Kurchatov Institute, Protvino, Russia

Institute for Theoretical and Experimental Physics named by A.I. Alikhanov of National Research Centre “Kurchatov Institute”, Moscow, Russia

Department of Physics, New York University, New York, New York, USA

Ochanomizu University, Otsuka, Bunkyo-ku, Tokyo, Japan

Ohio State University, Columbus, Ohio, USA

Homer L. Dodge Department of Physics and Astronomy, University of Oklahoma, Norman, Oklahoma, USA

Department of Physics, Oklahoma State University, Stillwater, Oklahoma, USA

Palacký University, RCPTM, Joint Laboratory of Optics, Olomouc, Czech Republic

Institute for Fundamental Science, University of Oregon, Eugene, Oregon, USA

Graduate School of Science, Osaka University, Osaka, Japan

Department of Physics, University of Oslo, Oslo, Norway

139x SLAC National Accelerator Laboratory, Stanford, California, USA
139y Physics Department, Royal Institute of Technology, Stockholm, Sweden
139z Departments of Physics and Astronomy, Stony Brook University, Stony Brook, New York, USA
140 Department of Physics, University of Sussex, Brighton, United Kingdom
140a School of Physics, University of Sydney, Sydney, Australia
140b Institute of Physics, Academia Sinica, Taipei, Taiwan
140c E. Andronikashvili Institute of Physics, Iv. Javakhishvili Tbilisi State University, Tbilisi, Georgia
140d High Energy Physics Institute, Tbilisi State University, Tbilisi, Georgia
140e Department of Physics, Technion, Israel Institute of Technology, Haifa, Israel
140f Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, Tel Aviv, Israel
140g Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece
140h International Center for Elementary Particle Physics and Department of Physics, University of Tokyo, Tokyo, Japan
140i Graduate School of Science and Technology, Tokyo Metropolitan University, Tokyo, Japan
140j Department of Physics, Tokyo Institute of Technology, Tokyo, Japan
140k Tomsk State University, Tomsk, Russia
140l Department of Physics, University of Toronto, Toronto ON, Canada
140m TRIUMF, Vancouver BC, Canada
140n Department of Physics and Astronomy, York University, Toronto ON, Canada
140o Division of Physics and Tomonaga Center for the History of the Universe, Faculty of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan
140p Department of Physics and Astronomy, Tufts University, Medford, Massachusetts, USA
140q Department of Physics and Astronomy, University of California Irvine, Irvine, California, USA
140r Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden
140s Department of Physics, University of Illinois, Urbana, Illinois, USA
140t Instituto de Física Corpuscular (IFIC), Centro Mixto Universidad de Valencia—CSIC, Valencia, Spain
140u Department of Physics, University of British Columbia, Vancouver BC, Canada
140v Department of Physics and Astronomy, University of Victoria, Victoria BC, Canada
140w Fakultät für Physik und Astronomie, Julius-Maximilians-Universität Würzburg, Würzburg, Germany

112006-27
177 Department of Physics, University of Warwick, Coventry, United Kingdom
178 Waseda University, Tokyo, Japan
179 Department of Particle Physics and Astrophysics, Weizmann Institute of Science, Rehovot, Israel
180 Department of Physics, University of Wisconsin, Madison, Wisconsin, USA
181 Fakultät für Mathematik und Naturwissenschaften, Fachgruppe Physik, Bergische Universität Wuppertal, Wuppertal, Germany
182 Department of Physics, Yale University, New Haven, Connecticut, USA

a Deceased.
b Also at Department of Physics, King’s College London, London, United Kingdom.
c Also at Instituto de Física Teórica, IFT-UAM/CSIC, Madrid, Spain.
d Also at TRIUMF, Vancouver BC, Canada.
e Also at Department of Physics and Astronomy, University of Louisville, Louisville, Kentucky, USA.
f Also at Physics Department, An-Najah National University, Nablus, Palestine.
g Also at Department of Physics, University of Fribourg, Fribourg, Switzerland.
h Also at Departament de Fisica de la Universitat Autonoma de Barcelona, Barcelona, Spain.
i Also at Moscow Institute of Physics and Technology State University, Dolgoprudny, Russia.
j Also at Department of Physics, Ben Gurion University of the Negev, Beer Sheva, Israel.
k Also at Universita di Napoli Parthenope, Napoli, Italy.
l Also at Institute of Particle Physics (IPP), Canada.
m Also at Dipartimento di Matematica, Informatica e Fisica, Università di Udine, Udine, Italy.

Also at Department of Physics, St. Petersburg State Polytechnical University, St. Petersburg, Russia.
Also at Borough of Manhattan Community College, City University of New York, New York, New York, USA.
Also at Department of Physics, California State University, Fresno, USA.
Also at Department of Financial and Management Engineering, University of the Aegean, Chios, Greece.
Also at Centro Studi e Ricerche Enrico Fermi, Italy.
Also at Department of Physics, California State University, East Bay, USA.
Also at Institut de Física d’Altes Energies, Universitat Autònoma de Barcelona, Bellaterra, Spain.
Also at IJCLab, Université Paris-Saclay, CNRS/IN2P3, 91405, Orsay, France.
Also at Graduate School of Science, Osaka University, Osaka, Japan.
Also at Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Freiburg, Germany.
Also at University of Chinese Academy of Sciences (UCAS), Beijing, China.
Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan.
Also at Institute for Mathematics, Astrophysics and Particle Physics, Radboud University Nijmegen/Nikhef, Nijmegen, Netherlands.
Also at CERN, Geneva, Switzerland.
Also at Joint Institute for Nuclear Research, Dubna, Russia.
Also at Hellenic Open University, Patras, Greece.
Also at The City College of New York, New York, New York, USA.
Also at Department of Physics, California State University, Sacramento, USA.
Also at Département de Physique Nucléaire et Corpusculaire, Université de Genève, Genève, Switzerland.
Also at Louisiana Tech University, Ruston, Louisiana, USA.
Also at Institute for Nuclear Research and Nuclear Energy (INRNE) of the Bulgarian Academy of Sciences, Sofia, Bulgaria.
Also at Faculty of Physics, M.V. Lomonosov Moscow State University, Moscow, Russia.
Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany.
Also at CPPM, Aix-Marseille Université, CNRS/IN2P3, Marseille, France.
Also at National Research Nuclear University MEPhI, Moscow, Russia.
Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary.
Also at Giresun University, Faculty of Engineering, Giresun, Turkey.
Also at Department of Physics and Astronomy, Michigan State University, East Lansing, Michigan, USA.
