ABSTRACT: We construct infinite new classes of AdS$_4 \times S^1 \times S^5$ solutions of type IIB string theory which have non-trivial SL(2, Z) monodromy along the $S^1$ direction. The solutions are supersymmetric and holographically dual, generically, to $\mathcal{N} = 1$ SCFTs in $d = 3$. The solutions are first constructed as AdS$_4 \times \mathbb{R}$ solutions in $D = 5$ SO(6) gauged supergravity and then uplifted to $D = 10$. Unlike the known AdS$_4 \times \mathbb{R}$ S-fold solutions, there is no continuous symmetry associated with the $\mathbb{R}$ direction. The solutions all arise as limiting cases of Janus solutions of $d = 4$, $\mathcal{N} = 4$ SYM theory which are supported both by a different value of the coupling constant on either side of the interface, as well as by fermion and boson mass deformations. As special cases, the construction recovers three known S-fold constructions, preserving $\mathcal{N} = 1, 2$ and 4 supersymmetry, as well as a recently constructed $\mathcal{N} = 1$ AdS$_4 \times S^1 \times S^5$ solution (not S-folded). We also present some novel “one-sided Janus” solutions that are non-singular.

1 Introduction

The landscape of non-geometric solutions of string/M-theory which are associated with the AdS/CFT correspondence is still largely unexplored territory. By definition, such solutions are patched together using duality symmetries and hence they are not ordinary solutions of the low-energy supergravity approximation. Nevertheless, in favourable situations one can still utilise supergravity constructions to obtain valuable insights.

Within the context of type IIB string theory, which is the focus of this paper, we can consider S-folds i.e. non-geometric solutions that are patched together using the $\text{SL}(2, \mathbb{Z})$ symmetry. For AdS/CFT applications we are interested in solutions of type IIB supergravity of the form $\text{AdS} \times M$ with, in general, the axion-dilaton, the three-forms and the self dual five-form all active on $M$. The S-fold construction implies that $M$ will have monodromies in $\text{SL}(2, \mathbb{Z})$, which act on the axion-dilaton and the three-forms. If these monodromies involve contractible loops in $M$ then, in general, one is led to the presence of brane singularities and regions where the supergravity approximation breaks down. However, one can hope to make further progress if the solutions lie within the context of F-theory as in the AdS$_3$ solutions discussed in [1, 2], for example.

We can also consider AdS $\times M$ solutions of type IIB supergravity where the $\text{SL}(2, \mathbb{Z})$ monodromies do not involve contractible loops. In this case, provided that the fields are all varying slowly on $M$, we can expect the type IIB supergravity approximation to be valid, and that such solutions do indeed correspond to dual CFTs. Examples of such solutions were presented in [3] and further discussed in [4]: the spacetime is of the form $\text{AdS}_4 \times S^1 \times S^5$ with non-trivial $\text{SL}(2, \mathbb{Z})$ monodromy just around the $S^1$ direction. The solutions preserve the supersymmetry associated with $\mathcal{N} = 4$ SCFTs in $d = 3$, and we shall refer to them as $\mathcal{N} = 4$ S-folds. These solutions can be constructed as a certain limit of a class of $\mathcal{N} = 4$ Janus solutions [5] which describe $\mathcal{N} = 4$, $d = 3$ superconformal interfaces of $d = 4$, $\mathcal{N} = 4$ SYM theory. Using this perspective, and the results of [6, 7], a specific conjecture for the SCFT dual to these $\mathcal{N} = 4$ S-folds was given in [4].

$\mathcal{N} = 1$ and $\mathcal{N} = 2$ S-fold solutions of the form $\text{AdS}_4 \times S^1 \times S^5$ have also been constructed in [8–10]. In particular, it was shown in [10] how they can be obtained as limiting solutions of $\mathcal{N} = 1$ [11–13] and $\mathcal{N} = 2$ [5] Janus solutions, also describing interfaces of $d = 4$, $\mathcal{N} = 4$ SYM theory. Furthermore, the $\mathcal{N} = 1$ $\text{AdS}_4 \times S^1 \times S^5$ S-folds have been generalised to $\mathcal{N} = 1$ $\text{AdS}_4 \times S^1 \times SE_5$ S-folds, where $SE_5$ is an arbitrary five-dimensional Sasaki-Einstein manifold [14].

In the Janus solutions that are used to construct the S-folds just mentioned [4, 10], the complex gauge coupling $\tau$ of $\mathcal{N} = 4$ SYM theory takes different values on either side of the interface. It was recently pointed out that this is not necessarily the case and it is possible to have interfaces in $\mathcal{N} = 4$ SYM with the same value of $\tau$ on either side of the interface which are supported by spatially dependent fermion and boson mass deformations, while preserving $d = 3$ conformal symmetry [15]. The associated supersymmetric Janus solutions of type IIB supergravity which are holographically dual to such interfaces were also constructed in [15] by first constructing them in $D = 5$ SO(6) gauged supergravity. Furthermore, there is a particularly interesting $\text{AdS}_4 \times \mathbb{R}$ solution that can be obtained as a
limit of this class of Janus solutions which is periodic in the $\mathbb{R}$ direction and uplifts to give a smooth\(^1\) $\text{AdS}_4 \times S^1 \times S^5$ solution of type IIB supergravity (i.e. with no S-folding) [15].

The constructions of [15] can be immediately generalised to give Janus solutions which have spatially dependent masses and varying $\tau$. It is therefore natural to ask if there are limiting classes of such Janus solutions which can be utilised to construct new S-fold solutions and/or periodic solutions. While we have not found any more periodic solutions, we have found infinite new classes of $\text{AdS}_4 \times \mathbb{R}$ solution of type IIB supergravity (i.e. with no S-folding) [15].

The constructions of [15] can be immediately generalised to give Janus solutions which have spatially dependent masses and varying $\tau$. It is therefore natural to ask if there are limiting classes of such Janus solutions which can be utilised to construct new S-fold solutions and/or periodic solutions. While we have not found any more periodic solutions, we have found infinite new classes of $\text{AdS}_4 \times \mathbb{R} \times S^5$ solution of type IIB supergravity (i.e. with no S-folding) [15].

Our new construction will utilise various consistent sub-truncations of $D = 5$ SO(6) gauged supergravity all lying within the 10-scalar truncation of [16] which, not surprisingly, just keeps 10 of the 42 scalars as well as the metric. One of these scalars, the $D = 5$ dilaton $\varphi$, which for the vacuum $\text{AdS}_5$ solutions is dual to the coupling constant of $\mathcal{N} = 4$ SYM theory, plays a privileged role as we expand upon below.\(^2\) Within this truncation we numerically construct families of $\text{AdS}_4 \times \mathbb{R}$ solutions that arise as certain limits of Janus solutions with $\mathcal{N} = 4$ SYM on either side of the interface. We then uplift these to obtain $\text{AdS}_4 \times \mathbb{R} \times S^5$ of type IIB supergravity, using the results of [17, 18]. Additional $\text{AdS}_4 \times \mathbb{R} \times S^5$ solutions in $D = 10$ can then be generated using SL(2,$\mathbb{R}$) transformations. Finally, within this larger family of solutions of type IIB supergravity one can find discrete examples where we can S-fold leading to supersymmetric $\text{AdS}_4 \times S^1 \times S^5$ S-fold solutions of type IIB string theory.

The $D = 5$ metric for the solutions we discuss in this paper are all of the form

$$ds^2 = e^{2A(r)}[ds^2(\text{AdS}_4) - dr^2],$$

with all of the $D = 5$ scalar fields just a function of the radial coordinate. The ansatz therefore preserves $d = 3$ conformal invariance. The $D = 5$ solutions associated with the known $\mathcal{N} = 1, 2$ and $4$ S-folds are all direct products of the form $\text{AdS}_4 \times \mathbb{R}$ with constant warp factor $A$ and with all of the $D = 5$ scalars constant, except for the $D = 5$ dilaton, $\varphi$, which varies linearly in the radial coordinate.

The new $\text{AdS}_4 \times \mathbb{R}$ solutions involve several novel features. First, the metric on $\text{AdS}_4 \times \mathbb{R}$ is no longer a direct product but a warped product, since the warp factor now has non-trivial dependence on the radial direction. Secondly, and importantly, the warp factor $A(r)$ and all of the $D = 5$ scalars are now periodic in the $\mathbb{R}$ direction, with the same period $\Delta r$, except for $\varphi$ which is now a “linear plus periodic” (LPP) function of $r$. Thus, unlike the known $\text{AdS}_4 \times \mathbb{R}$ S-fold solutions, the metric no longer admits a Killing vector associated with translations in the $\mathbb{R}$ direction and, furthermore, the solution is no longer invariant under the continuous symmetry consisting of translating along the $\mathbb{R}$ direction combined with a suitable dilaton shift. Thirdly, and as a consequence of the latter, we do not believe that the new solutions can be constructed in the maximally supersymmetric $D = 4$ gauged supergravity theory which can be used to construct the known S-fold solutions [3, 8, 9].

\(^1\) As far as we are aware this is the first example of a supersymmetric $\text{AdS}_4 \times M_6$ solution of type IIB supergravity, with compact $M_6$ that is smooth i.e. without sources.

\(^2\) We note that, in general, the type IIB dilaton of the uplifted solutions is not the same as the $D = 5$ dilaton, as explained in appendix A.
This is simply because the $D = 4$ theory is expected to arise after carrying out a Scherk-Schwarz dimensional reduction of maximal $D = 5$ gauged supergravity on the $\mathbb{R}$ direction and this reduction requires such a continuous symmetry. In figure 1 we have illustrated how the new solutions arise as limiting cases of Janus solutions of $\mathcal{N} = 4$ SYM which, generically, have the $\mathcal{N} = 4$ SYM coupling taking different values on either side of the interface, as well as additional fermion and boson mass deformations.

The plan of the paper is as follows. We begin in section 2 by discussing the 10-scalar truncation of maximal $D = 5$ SO(6) gauged supergravity given in [16] as well as various sub-truncations. In section 3 we discuss the general framework for constructing the new $\text{AdS}_4 \times \mathbb{R}$ solutions in $D = 5$ and the procedure for then obtaining $\text{AdS}_4 \times S^1 \times S^5$ S-folds solutions of type IIB string theory.

In sections 4 and 5 we discuss in more detail the constructions for two particular sub-truncations: an $\text{SO}(3) \subset \text{SU}(3) \subset \text{SO}(6)$ invariant model involving four scalar fields and an $\text{SU}(2) \subset \text{SU}(3) \subset \text{SO}(6)$ invariant model involving five scalar fields. The $\text{SO}(3)$ invariant model, called the $\mathcal{N} = 1^*$ equal mass model in [15], includes the $\text{AdS}_4 \times \mathbb{R}$ solutions associated with the known $\mathcal{N} = 1$ and $\mathcal{N} = 4$ S-fold solutions as well as the periodic $\text{AdS}_4 \times \mathbb{R}$ solution found in [15]. We note that figure 1 is associated with this model. The $\text{SU}(2)$ invariant model includes the $\text{AdS}_4 \times \mathbb{R}$ solutions associated with the known $\mathcal{N} = 2$ S-fold solutions and it also includes those associated with the known $\mathcal{N} = 1$ S-fold solutions. In both truncations, our new family of S-fold solutions includes the previous known solutions. Furthermore, in both cases one can identify the existence of some of our new family of solutions by a perturbative construction about the known $\mathcal{N} = 1$ S-fold solution (but, interestingly, not around the $\mathcal{N} = 2, 4$ solutions).
In section 6 we briefly discuss some novel “one-sided Janus” solutions which approach the AdS\(_5\) vacuum on one side and either a known S-fold solution, an LPP dilaton solution or the periodic \(D = 5\) solution of [15] on the other. Unlike other one-sided Janus solutions, they are non-singular. In the case that it approaches the \(N = 4\) AdS\(_4\) × \(\mathbb{R}\) S-fold solution we are able to construct the solution analytically and we show how, after uplifting to type IIB supergravity, it fits into the general class of AdS\(_4\) × \(S^2\) × \(S^2\) × \(\Sigma\) solutions preserving \(N = 4\) supersymmetry that were studied in [19, 20] (see also [21–23] for some later developments). We also discuss how the solution is related to solutions describing D3-branes ending on D5-branes. In appendix A we have included some useful results concerning how to uplift solutions of the 10-scalar model in \(D = 5\) to type IIB supergravity. In appendix B, prompted by the analysis in section 6, we refine the holographic renormalisation analysis for the 10-scalar truncation of [15] in a way that is consistent with the preservation of additional supersymmetry in the boundary theory.

2 The 10-scalar model

We are interested in a truncation of \(\mathcal{N} = 8\), SO(6) gauged supergravity in \(D = 5\), discussed in [16], that involves the metric and ten scalar fields which parametrise the coset

\[
\mathcal{M}_{10} = \text{SO}(1, 1) \times \text{SO}(1, 1) \times \left[ \frac{\text{SU}(1, 1)}{\text{U}(1)} \right]^4.
\]

(2.1)

The SO(1, 1) × SO(1, 1) is parametrised by two scalars \(\beta_1, \beta_2\) while the remaining eight scalars of this truncation, parametrising four copies of the Poincaré disc, can be packaged into four complex scalar fields \(z^A\) via

\[
\begin{align*}
    z^1 &= \tanh \left[ \frac{1}{2} (\alpha_1 + \alpha_2 + \alpha_3 + \varphi - i\phi_1 - i\phi_2 - i\phi_3 + i\phi_4) \right], \\
    z^2 &= \tanh \left[ \frac{1}{2} (\alpha_1 - \alpha_2 + \alpha_3 - \varphi - i\phi_1 + i\phi_2 - i\phi_3 - i\phi_4) \right], \\
    z^3 &= \tanh \left[ \frac{1}{2} (\alpha_1 + \alpha_2 - \alpha_3 - \varphi - i\phi_1 - i\phi_2 + i\phi_3 - i\phi_4) \right], \\
    z^4 &= \tanh \left[ \frac{1}{2} (\alpha_1 - \alpha_2 - \alpha_3 + \varphi - i\phi_1 + i\phi_2 + i\phi_3 + i\phi_4) \right].
\end{align*}
\]

(2.2)

Schematically, these 10 scalar fields are dual to the following Hermitian operators in \(\mathcal{N} = 4\) SYM theory:

\[
\begin{align*}
    \Delta = 4 : & \quad \varphi \leftrightarrow \text{tr}F_{\mu\nu}F^{\mu\nu}, \\
    \Delta = 3 : & \quad \phi_i \leftrightarrow \text{tr}(\chi_i\chi_i + \text{cubic in } Z_i) + h.c., \quad i = 1, 2, 3, \\
    \phi_4 & \leftrightarrow \text{tr}(\lambda\lambda + \text{cubic in } Z_i) + h.c., \\
    \Delta = 2 : & \quad \alpha_i \leftrightarrow \text{tr}(Z_i^2) + h.c., \quad i = 1, 2, 3, \\
    \beta_1 & \leftrightarrow \text{tr}(|Z_1|^2 + |Z_2|^2 - 2|Z_3|^2), \\
    \beta_2 & \leftrightarrow \text{tr}(|Z_1|^2 - |Z_2|^2).
\end{align*}
\]

(2.3)
The operators of $d = 4$, $\mathcal{N} = 4$ SYM appearing on the right hand side of (2.3) have been written in an $\mathcal{N} = 1$ language, with $Z_i$ and $\chi_i$ the bosonic and fermionic components of the associated three chiral superfields $\Phi_i$ while $\lambda$ is the gaugino of the vector multiplet. Thus, the $D = 5$ dilaton $\varphi$ is dual to the coupling constant of $\mathcal{N} = 4$ SYM theory, while $\phi_i, \phi_4$ are fermionic mass terms and $\alpha_i, \beta_1, \beta_2$ are bosonic mass terms.

The action is given by

$$S_{\text{Bulk}} = \frac{1}{4\pi G_{(5)}} \int d^5x \sqrt{|g|} \left[ -\frac{1}{4} R + 3(\partial \beta_1)^2 + (\partial \beta_2)^2 + \frac{1}{2} K_{\alpha\beta} \partial \varphi z^A \partial \bar{z}^\beta - \mathcal{P} \right],$$

(2.4)

and we work with a (+ − − − −) signature convention. Here $K$ is the Kähler potential given by

$$K = -\sum_{A=1}^{4} \log(1 - z^A \bar{z}^A).$$

(2.5)

The scalar potential $\mathcal{P}$ can be conveniently derived from a superpotential-like quantity

$$\mathcal{W} \equiv \frac{1}{L} e^{2\beta_1 + 2\beta_2} \left( 1 + z^1 z^2 + z^1 z^3 + z^1 z^4 + z^2 z^3 + z^2 z^4 + z^3 z^4 + z^4 z^4 \right)
+ \frac{1}{L} e^{2\beta_1 - 2\beta_2} \left( 1 - z^1 z^2 + z^1 z^3 - z^1 z^4 - z^2 z^3 + z^2 z^4 - z^3 z^4 + z^4 z^4 \right)
+ \frac{1}{L} e^{-4\beta_1} \left( 1 + z^1 z^2 - z^1 z^3 - z^1 z^4 - z^2 z^3 + z^2 z^4 + z^3 z^4 + z^4 z^4 \right),$$

(2.6)

via

$$\mathcal{P} = \frac{1}{8} e^K \left[ \frac{1}{6} \partial \beta_1 \mathcal{W} \partial \beta_1 \mathcal{W} + \frac{1}{2} \partial \beta_2 \mathcal{W} \partial \beta_2 \mathcal{W} + K B^A \nabla_A \mathcal{W} \nabla_B \mathcal{W} - \frac{8}{3} \mathcal{W}^2 \right].$$

(2.7)

where $K^{BA}$ is the inverse of $K_{AB}$ and $\nabla_A \mathcal{W} \equiv \partial_A \mathcal{W} + \partial_A K \mathcal{W}$.

The model is invariant under $\mathbb{Z}_2 \times S_4$ discrete symmetries which, importantly, leave $\mathcal{W}$ invariant. First, it is invariant under the $\mathbb{Z}_2$ symmetry

$$z^A \to -z^A, \quad \Leftrightarrow \quad \{\phi_i, \phi_4, \alpha_i, \varphi\} \to -\{\phi_i, \phi_4, \alpha_i, \varphi\}.$$

(2.8)

Second, it is invariant under an $S_3$ permutation symmetry which acts on $(-z^2, -z^3, z^4)$ as well as $\beta_1, \beta_2$ and is generated by two elements:

$$\begin{align*}
\{z^3 \leftrightarrow z^4 & \} \quad \Leftrightarrow \quad \phi_1 \leftrightarrow \phi_3, \alpha_1 \leftrightarrow \alpha_3, \quad \beta_1 \to -\frac{1}{2}(\beta_1 + \beta_2), \quad \beta_2 \to \frac{1}{2}(\beta_2 - 3\beta_1), \\
\{z^2 \leftrightarrow z^4 & \} \quad \Leftrightarrow \quad \phi_1 \leftrightarrow \phi_2, \alpha_1 \leftrightarrow \alpha_2, \quad \beta_2 \to -\beta_2.
\end{align*}$$

(2.9)

There is also an invariance under the interchange of pairs of the $z^A$:

$$\begin{align*}
z^1 \leftrightarrow z^4, \quad & z^2 \leftrightarrow -z^3, \quad \Leftrightarrow \quad (\phi_2, \phi_3) \to -(\phi_2, \phi_3), \quad (\alpha_2, \alpha_3) \to -(\alpha_2, \alpha_3), \\
z^1 \leftrightarrow -z^2, \quad & z^3 \leftrightarrow z^4, \quad \Leftrightarrow \quad (\phi_1, \phi_3) \to -(\phi_1, \phi_3), \quad (\alpha_1, \alpha_3) \to -(\alpha_1, \alpha_3), \\
z^1 \leftrightarrow -z^3, \quad & z^2 \leftrightarrow z^4, \quad \Leftrightarrow \quad (\phi_1, \phi_2) \to -(\phi_1, \phi_2), \quad (\alpha_1, \alpha_2) \to -(\alpha_1, \alpha_2).
\end{align*}$$

(2.10)
Together (2.8)–(2.10) generate $\mathbb{Z}_2 \times S_4$ as observed in [24]. We also note that (2.9), (2.10) are discrete subgroups of the $\text{SO}(6)$ R-symmetry while (2.8) is part of the $\text{SL}(2, \mathbb{R})$ symmetry of $D = 5$ gauged supergravity.

The model is also invariant under shifts of the dilaton

$$\varphi \to \varphi + c. \quad (2.11)$$

For later use, we note that this shift symmetry is generated by the following holomorphic Killing vector

$$l = \frac{1}{2} \sum_{A=1}^{4} (-1)^{s(A)} (1 - (z^A)^2) \frac{\partial}{\partial z^A}, \quad (2.12)$$

where $s(A) = 0$ for $A = 1, 4$ and $s(A) = 1$ for $A = 2, 3$. Furthermore, if we define

$$\tilde{\mathcal{K}} \equiv \mathcal{K} + \log \mathcal{W} + \log \bar{\mathcal{W}}, \quad (2.13)$$

we have

$$l^A \partial_A \tilde{\mathcal{K}} + l^B \partial_B \tilde{\mathcal{K}} = 0, \quad (2.14)$$

and the corresponding moment map $\mu = \mu(z^A, \bar{z}^A)$, satisfying

$$\mu = i l^A \partial_A \tilde{\mathcal{K}} = \mathcal{K}^{AB} \partial_B \mu \partial_A \tilde{\mathcal{K}}, \quad (2.15)$$

is given by

$$\mu = -\frac{i}{2} \sum_{A=1}^{4} (-1)^{s(A)} \frac{z^A - \bar{z}^A}{1 - z^A \bar{z}^A}. \quad (2.16)$$

In terms of the fields given in (2.2) we find that the moment map only depends on $\phi_1, \phi_4$ and takes the form

$$\mu = \frac{1}{2} \left[ \tan(-\phi_1 - \phi_2 - \phi_3 + \phi_4) - \tan(-\phi_1 + \phi_2 - \phi_3 - \phi_4) \right. \quad (2.17)$$

$$\left. - \tan(-\phi_1 - \phi_2 + \phi_3 - \phi_4) + \tan(-\phi_1 + \phi_2 + \phi_3 + \phi_4) \right].$$

Expanding about $\phi_1 = 0$ we have to lowest order $\mu \sim 2\phi_4$.

The 10-scalar truncation is not a supergravity theory. However, the conditions for a solution of the 10-scalar model to preserve a preferred supersymmetry as a solution of $D = 5$ $\text{SO}(6)$ gauged supergravity were written down in [16] and also used in [15]. These preferred supersymmetry transformations are left invariant under the $\mathbb{Z}_2 \times S_4$ discrete symmetries (2.8)–(2.10). The equations of motion of the 10-scalar model are also invariant under additional discrete symmetries, given in appendix B, which transform the supercharges of the maximal $D = 5$ gauged supergravity theory into each other and do not preserve the preferred supersymmetries that we focus on in this paper. Here we use exactly the same conventions as [15].

There are a number of different consistent sub-truncations of the 10-scalar model which were also discussed in [16], that we summarise in figure 2. The figure also displays where
one can find the three known AdS$_4 \times \mathbb{R}$ solutions with a linear $D = 5$ dilaton $\varphi$ which are associated with S-folds preserving $\mathcal{N} = 1, 2$ and 4 supersymmetry, as well as the symmetry subgroup of SO(6) that is preserved by the truncation. These sub-truncations preserve various subsets of the $\mathbb{Z}_2 \times S_4$ discrete symmetries given in (2.8)–(2.10). All of the sub-truncations preserve the $\mathbb{Z}_2$ symmetry (2.8) as well as shifts of the dilaton (2.11) when the dilaton $\varphi$ is present in the truncation. In this paper we will be mostly interested in two cases: the $\mathcal{N} = 1^*$ equal mass, SO(3) invariant model, with SO(3) $\subset$ SU(3) $\subset$ SU(4) and involving four scalar fields; and the 5-scalar SU(2) invariant model, with SU(2) $\subset$ SU(3) $\subset$ SU(4). While the SO(3) invariant model does not preserve any additional symmetries, the SU(2) model preserves a further $\mathbb{Z}_2$ that is contained in (2.10).

3 Constructing S-folds

The construction of the S-fold solutions starts with solutions of $D = 5$ supergravity. These are then uplifted to type IIB, where additional solutions are generated using the SL(2, $\mathbb{R}$) symmetry of type IIB supergravity. Finally, the S-folding procedure, using the SL(2, $\mathbb{Z}$) symmetry of type IIB string theory, is made.

3.1 Ansatz in $D = 5$

We consider solutions of $D = 5$ supergravity of the form

$$ds^2 = e^{2A}ds^2(\text{AdS}_4) - N^2dv^2,$$

(3.1)
where $ds^2(\text{AdS}_4)$ is the metric on $\text{AdS}_4$, which we take to have unit radius, and $A$, $N$ as well as the scalar fields $\beta_1, \beta_2, z^A$ are functions of $r$ only. Clearly this ansatz preserves $d = 3$ conformal invariance. There is still some freedom in choosing the radial coordinate. In this paper we will either use the “conformal gauge” with $N = e^A$, as in (1.1), or the “proper distance gauge” with $N = 1$

\begin{align}
\text{conformal gauge: } N &= e^A, \quad \text{radial coordinate: } r, \\
\text{proper distance gauge: } N &= 1, \quad \text{radial coordinate: } \bar{r},
\end{align}

with $d\bar{r} = e^A dr$.

We are interested in supersymmetric configurations which, generically, are associated with $N = 1$ supersymmetry in $d = 3$ (i.e. two Poincaré plus two superconformal supercharges). As shown in [15], we obtain such solutions provided that we satisfy the following BPS equations (in the conformal gauge),

\begin{align}
\partial_r A - i &= 2B_r, \\
\partial_r B_r &= 2\mathcal{F} B_r \bar{B}_r,
\end{align}

where $\mathcal{F}$ is a real quantity just depending on $W$, $K$ given by

\begin{align}
\mathcal{F} &= 1 - \frac{3}{2} \frac{1}{|W|^2} \nabla_A W K^{AB} \nabla_B \bar{W} - \frac{1}{4} |\partial_{\beta_1} \log W|^2 - \frac{3}{4} |\partial_{\beta_2} \log W|^2,
\end{align}

as well as

\begin{align}
\partial_r z^A &= -3K^{AB} \frac{\nabla_B \bar{W}}{\bar{W}} B_r, \\
\partial_r \beta_1 &= -\frac{1}{2} \partial_{\beta_1} \log \bar{W} B_r, \\
\partial_r \beta_2 &= -\frac{3}{2} \partial_{\beta_2} \log \bar{W} B_r.
\end{align}

In these equations the quantity $B_r$ is defined as $B_r \equiv \frac{1}{6} e^{\xi + K/2} W$ where $\xi(r)$ is a phase that appears in the Killing spinors. It is helpful to point out that the BPS equations are left invariant under the transformation

\begin{align}
r \to -r, \quad z^A \to \bar{z}^A, \quad \xi \to -\xi + \pi.
\end{align}

The BPS equations are also invariant under the discrete $\mathbb{Z}_2 \times S_4$ symmetries in (2.8)–(2.10) and this will also be the case for any of the sub-truncations in figure 2 for which they are still present. Additional general aspects of the space of solutions to these BPS equations were discussed in section 5 of [15].

---

3With essentially no loss of generality, the parameter $\kappa = \pm 1$ appearing in [15], which fixes the projections on the Killing spinors, has been set to $\kappa = +1$.

4In general, the transformation $z^A \to \bar{z}^A$ by itself, which can be obtained by combining (B.2) with (2.8)-(2.10), is a symmetry of the equations of motion for the 10-scalar model but also acts on the preferred supersymmetries.
It will also be useful to notice that the dilaton shift symmetry (2.11) of the 10-scalar model gives rise to a conserved quantity for the BPS equations. Specifically, using (2.15) one can check that an integral of motion for the BPS equations is given by

\[ E \equiv \frac{1}{L^3} e^{3A} \mu(z, \bar{z}), \]  

where the moment map was given in (2.16) or (2.17). This result can be derived via the Noether procedure as follows. The Killing vector \( l^A \) generating the symmetry (2.11), gives rise to a conserved current for the full equations of motion. For our radial ansatz we deduce that the radial component of this current, given by

\[ E \propto \sqrt{g} g^{rr} (K^A \bar{B} \partial_r \bar{z} \bar{B} l^A + K^B \partial_r z B l^A), \]  

is a conserved quantity, independent of \( r \). Using the BPS equations we then obtain

\[ E \propto e^{3A} \left( \partial_A \tilde{K} B_r l^A + \partial_A \tilde{K} B_r l^A \right), \]

\[ = e^{3A} \left( (l^A \partial_A \tilde{K} + l^A \partial_A \tilde{K}) \text{Re}(B_r) - \frac{i}{2} (l^A \partial_A \tilde{K} - l^A \partial_A \tilde{K}) \right), \]

\[ = -e^{3A} (il^A \partial_A \tilde{K}) = -e^{3A} \mu, \]  

where to get to the second line we wrote \( B_r = \text{Re}(B_r) - \frac{i}{2} \), and to get to the third line we used (2.14) and (2.15).

### 3.2 Janus solutions

We now briefly summarise some aspects of the Janus solutions constructed in [15]. We first recall that the AdS\(_5\) vacuum solution, dual to \( d = 4, \mathcal{N} = 4 \) SYM, has a warp factor given by

\[ e^A = L \cosh \frac{\bar{r}}{L}, \]  

with all of the scalars vanishing, \( z^A = 0 \).

Janus solutions, describing superconformal interfaces of \( d = 4, \mathcal{N} = 4 \) SYM, can be obtained by solving the BPS equations and imposing boundary conditions so that they approach the AdS\(_5\) vacuum solution (3.10) at \( \bar{r} = \pm \infty \), with suitable falloffs for the scalar fields, associated with supersymmetric sources for the dual operators. A detailed analysis of holographic renormalisation for such Janus solutions was carried out in [15] (using the proper distance gauge). The focus in [15] was to construct Janus solutions that are dual to interfaces of \( \mathcal{N} = 4 \) SYM that are supported by fermion and boson masses that have a non-trivial spatial dependence on the direction transverse to the interface. These solutions were constructed within the following truncations, shown in green boxes in figure 2: the \( \mathcal{N} = 2^* \) truncation (three scalar fields), the \( \mathcal{N} = 1^* \) one-mass truncation (three scalar fields) and the \( \mathcal{N} = 1^* \) equal-mass, SO(3) invariant truncation (four scalar fields).

Within the Janus solutions of the \( \mathcal{N} = 1^* \) equal-mass, SO(3) invariant truncation (green and red box in figure 2) a special limiting AdS\(_4\) \( \times \mathbb{R} \) solution was found with the warp factor \( A \) and all of the scalar fields periodic in the \( \mathbb{R} \) direction. As such, this solution
can be compactified on the $R$ direction and after uplifting to type IIB, one obtains a regular $\text{AdS}_4 \times S^1 \times S^5$ solution (without S-folding). In the sequel we will present new $\text{AdS}_4 \times R$ solutions which are no longer periodic in the $R$ direction that can also be found as limiting classes of Janus solutions. In the new solutions the $D = 5$ dilaton, $\varphi$, is a LPP function while the remaining scalars and warp factor are periodic in the $R$ direction; an illustration is given in figure 1. All of our new S-fold solutions arise as limits of $D = 5$ Janus solutions with $\varphi_{(s)}$, which parametrises the source for the operator dual to $\varphi$, taking different values on either side of the interface. In other words the Janus solutions are interfaces of $\text{AdS}_3$.3

find that the integral of motion is given by well the conditions on sources and expectation values imposed by the BPS conditions, we be used to obtain the expectation values, explicitly given in [15]. Using this expansion as $\phi$ Here $N$ is given in figure 1. All of our new S-fold solutions arise as limits of $D = 5$ Janus solutions with the LS theory on either side of the interface. In this paper we also construct solutions within the 5-scalar $\text{SU}(2)$ truncation in figure 2 (red box), which contain the LS$^\pm$ fixed points. In addition to the new LPP solutions we also find limiting Janus solutions that involve Janus interfaces for the LS theory on either side of the interface. In other words the Janus solutions are interfaces of $\text{AdS}_3$.3

$\partial_{(s)}\mathcal{O}(\varphi_{(s)},\bar{\varphi}_{(s)}) = \mathcal{O}(\varphi_{(v)},\bar{\varphi}_{(v)})$, which used the proper distance gauge, the expansion at, say, the interface is given by

in [15], which used the proper distance gauge, the expansion at, say, the end of the $\text{AdS}_3$.3 direction; an illustration

Finally, as somewhat of an aside, we note that the conserved quantity $\mathcal{E}$ given in (3.7) implies a constraint amongst the sources and expectation values of operators of $N = 4$ SYM theory for the Janus configurations. Following the holographic renormalisation carried out in [15], which used the proper distance gauge, the expansion at, say, the $\bar{r} \to \infty$ end of the interface is given by

$\varphi = \varphi_{(s)} + \cdots + \varphi_{(v)} e^{-4\bar{r}/L} + \cdots$, 

$A = \bar{r}/L + \cdots + A_{(v)} e^{-4\bar{r}/L} + \cdots$. \hspace{1cm} (3.11)

Here $\phi_{(s)}, \alpha_{(s)}, \cdots$ give the source terms of the dual operators, while $\phi_{(v)}, \alpha_{(v)}, \cdots$ can be used to obtain the expectation values, explicitly given in [15]. Using this expansion as well the conditions on sources and expectation values imposed by the BPS conditions, we find that the integral of motion is given by

$\mathcal{E} = \frac{1}{L^3} (2\phi_{(v)} - 4\phi_{(s)} \phi_{2,(s)} \phi_{3,(s)})$. \hspace{1cm} (3.12)

3.3 $\text{AdS}_4 \times R$ solutions and S-folds

Our principal interest in this paper concerns a new class of solutions to the BPS equations of the form (in conformal gauge):

$ds^2 = e^{2A}[ds^2(\text{AdS}_4) - dr^2]$, 

$\varphi = kr + f(r)$, \hspace{1cm} (3.13)
where $k$ is a constant and $A, f$ and all other scalars satisfy

$$A(r) = A(r + \Delta r), \quad f(r) = f(r + \Delta r), \quad z^A(r) = z^A(r + \Delta r). \quad (3.14)$$

Notice that, in general, the $D = 5$ dilaton $\varphi$ is an LPP function, while the warp factor and the remaining scalar fields are all periodic functions of $r$, with period $\Delta r$. Over one period $\varphi$ changes by an amount $\Delta \varphi$ given by

$$\Delta \varphi \equiv \varphi(r + \Delta r) - \varphi(r) = k \Delta r. \quad (3.15)$$

Although we have defined $\Delta \varphi$ in the conformal gauge, importantly (and unlike $k, \Delta r$) it is invariant under coordinate changes$^5$ of the form $r \rightarrow \rho$ with $d \rho = G(r) dr$ where $G(r)$ is a periodic function, $G(r + \Delta r) = G(r)$. We can also define the proper distance of a period $\Delta \tilde{r}$, which is given by

$$\Delta \tilde{r} = \int_0^{\Delta r} e^A dr. \quad (3.16)$$

For the special case when $k = 0$, when $\varphi$ is also periodic, these solutions are periodic in the $r$ direction and we can then immediately compactify the radial direction to obtain an $\text{AdS}_4 \times S^1$ solution. In this case, if we identify after just one period, $\Delta \tilde{r}$ is the length of the $S^1$. We presented one such solution in [15] and this will appear in our new constructions. For this purely periodic solution the period of the warp factor is half of that of the scalar fields. Another special case is when $k \neq 0$ and $f = 0$, so that $\varphi$ is purely linear in $r$, as well as $A$ and all other scalar fields being constant. These $\text{AdS}_4 \times \mathbb{R}$ solutions are associated with the known AdS$_4$ S-fold solutions: we can periodically identify the radial direction after uplifting to type IIB supergravity and making a suitable identification with an $\text{SL}(2, \mathbb{Z})$ transformation, as we outline in more generality below.

We now continue with the more general class of LPP solutions of the form (3.13) with both $k \neq 0$ and $f \neq 0$ and show that these too can give rise to new classes of $\text{AdS}_4$ S-fold solutions. We begin by noting, as explained in appendix A (see also [10]), that the dilaton-shift symmetry (2.11) of the $D = 5$ theory, $\varphi \rightarrow \varphi + c$, acts as a specific $\text{SL}(2, \mathbb{R})$ transformation in $D = 10$. If the type IIB dilaton, $\Phi$ and axion $C_0$ are parametrised as

$$m_{\alpha\beta} = \begin{pmatrix} e^\Phi C_0 & e^\Phi - e^\Phi C_0 \\ -e^{-\Phi} C_0 & e^\Phi \end{pmatrix}, \quad (3.17)$$

then the transformation is given by $m \rightarrow (S^{-1})^T m S^{-1}$ where $S \in \text{SL}(2, \mathbb{R})$, in the hyperbolic conjugacy class, is given by

$$S(c) = \begin{pmatrix} e^c & 0 \\ 0 & e^{-c} \end{pmatrix}. \quad (3.18)$$

Equivalently, we have $\Phi \rightarrow \Phi + 2c$ and $C_0 \rightarrow e^{-2c} C_0$.

---

$^5$After integrating we can write $\rho = cr + H(r)$ with $H(r + \Delta r) = H(r)$ and $H$ having no zero mode. Inverting this, we can write $r = (1/c) \rho + \hat{H}(\rho)$ with $\hat{H}(\rho + \Delta \rho) = \hat{H}(\rho)$, where $\Delta \rho = c \Delta r$. In this gauge we can then write $\varphi = (k/c) \rho + \hat{f}(\rho)$ with $\hat{f}(\rho + \Delta \rho) = \hat{f}(\rho)$ and $\Delta \varphi = k \Delta r$. 

- 11 -
To carry out the S-fold procedure, we next note that starting from the uplifted $D=5$ solutions we can obtain a family of uplifted type IIB solutions after acting with a general element $P \in SL(2, \mathbb{R})$. For example, the axion and dilaton in this larger family will be of the form $\tilde{m}(\varphi) = (P^{-1})^T m(\varphi) P^{-1}$, where we have included the dependence on the $D=5$ dilaton for emphasis. Within this larger family of type IIB solutions we then look for solutions that we can periodically identify along the radial direction with period $q \Delta r$ i.e. $q \in \mathbb{N}$ times the fundamental period $\Delta r$, up to the action of an $M \in SL(2, \mathbb{Z})$ transformation. Recalling that as we translate by $\Delta r$ in the radial direction in the conformal gauge (3.13) we have $\varphi \to \varphi + \Delta \varphi$, and hence we require that

$$\tilde{m}(\varphi + q \Delta \varphi) = (M^{-1})^T \tilde{m}(\varphi) M^{-1},$$

which can be achieved provided that $P \in SL(2, \mathbb{R})$ is such that

$$M = \pm P S(q \Delta \varphi) P^{-1}. \quad (3.20)$$

The different S-folded solutions which can be obtained in this way are labelled by the conjugacy classes of $M$ in $SL(2, \mathbb{Z})$. A discussion of such classes can be found in [26, 27] (see also [28]). For any conjugacy class $M$, we have that $-M$ and $\pm M^{-1}$ also represent conjugacy classes. Clearly from the form of $S$ in (3.18) we must be in the hyperbolic conjugacy class with $|Tr(M)| > 2$. We have the following possibilities for $M$ (as well as the conjugacy classes $-M$ and $\pm M^{-1}$): we can have

$$M = \begin{pmatrix} n & 1 \\ -1 & 0 \end{pmatrix}, \quad n \geq 3, \quad (3.21)$$

with trace $n$, as well as “sporadic cases” $M(t)$ of trace $t$. For example for $3 \leq t \leq 12$ the complete list is given by

$$M(8) = \begin{pmatrix} 1 & 2 \\ 3 & 7 \end{pmatrix}, \quad M(10) = \begin{pmatrix} 1 & 4 \\ 2 & 9 \end{pmatrix}, \quad M(12) = \begin{pmatrix} 1 & 2 \\ 5 & 11 \end{pmatrix}. \quad (3.22)$$

For these cases, in order to find solutions to (3.19) (focussing on the upper sign in (3.20)) we must have

$$q \Delta \varphi = \arccosh \frac{n}{2}, \quad \text{for} \quad n \geq 3, \quad q \geq 1. \quad (3.23)$$

For example, for the S-folds that are identified using $M$ in $SL(2, \mathbb{Z})$ given in (3.21) we have

$$P = \begin{pmatrix} 1 \\ -n + \sqrt{n^2 - 4} \end{pmatrix} \frac{1}{2} \begin{pmatrix} 1 + \frac{n}{\sqrt{n^2 - 4}} \end{pmatrix}. \quad (3.24)$$

Interestingly, the S-folding procedure preserves the supersymmetry as we now explain. If we translate the $D=5$ solution by $\Delta r$ then we have $\varphi \to \varphi + \Delta \varphi$. Such a shift in the
dilaton is equivalently obtained by carrying out a Kähler transformation $K \rightarrow K + f + \bar{f}$ and $W \rightarrow e^{-f}W$ with $f = f(z^A)$. Under this transformation the preserved supersymmetries, a symplectic Majorana pair, transform as $\varepsilon_1 \rightarrow e^{(f - \bar{f})/4} \varepsilon_1$ and $\varepsilon_2 \rightarrow e^{-(f - \bar{f})/4} \varepsilon_2$ as noted in [15]. Now, as we explained above, this transformation is implemented on the bosonic fields as an element of $S \in SL(2, \mathbb{R})$. In appendix A we show that this is also true for the preserved supersymmetries. Thus, as we translate by $\Delta r$, the solution and the preserved supersymmetries get transformed by the same element of $SL(2, \mathbb{R})$. This will also be true after uplifting to $D = 10$ and hence, after conjugating by $P \in SL(2, \mathbb{R})$, the S-fold procedure will not break any supersymmetry.

### 3.4 Free energy of the S-folds

The $\text{AdS}_4 \times S^1 \times S^5$ S-fold solutions of the kind we have just described should be dual, in general, to $\mathcal{N} = 1$ SCFTs in $d = 3$. A key observable is $\mathcal{F}_{S^3}$, the free energy of the SCFT on $S^3$. This can be calculated holographically after a dimensional reduction on $S^1 \times S^5$ to a four-dimensional theory of gravity and then evaluating the regularised on-shell action for the $\text{AdS}_4$ vacuum solution of this theory. With a four-dimensional theory that has an $\text{AdS}_4$ vacuum solution with unit radius we have

$$\mathcal{F}_{S^3} = \frac{\pi}{2G(4)}.\quad (3.25)$$

Here $G(4)$ is the four-dimensional Newton’s constant which can be obtained from the five-dimensional Newton’s constant via

$$\frac{1}{G(4)} = \frac{1}{G(5)} \int_0^q d\rho \epsilon^{3A}.\quad (3.26)$$

Here we remind the reader that the radial coordinate, $r$, is associated with the $D = 5$ conformal gauge, as in (3.13), and also that in the construction of the S-fold solution we made the S-fold identification after going along $q$ periods of the periodic functions. Recalling that the $\text{AdS}_5$ vacuum with radius $L$ solves the equations of motion and is dual to $d = 4$, $\mathcal{N} = 4\text{SYM}$ with gauge group $SU(N)$, we have the standard result

$$\frac{1}{16\pi G(5)} = \frac{N^2}{8\pi^2 L^3}.\quad (3.27)$$

Putting this together we get our final formula for the free energy:

$$\mathcal{F}_{S^3} = \frac{N^2}{L^3 q} \int_0^{\Delta r} d\rho \epsilon^{3A},$$

$$= \frac{N^2}{L^3} \arccosh \frac{q}{2} \int_0^{\Delta r} d\rho \epsilon^{3A}.\quad (3.28)$$

The first expression is valid for all solutions, including the periodic solution (for which it is natural to take $q = 1$), while the second expression is valid for the S-folded solutions. In the special case of the known $\mathcal{N} = 1, 2, 4$ S-folds which have a purely linear $D = 5$ dilaton (i.e. $\varphi = kr$ in (3.13)) and $A$ is constant, we can rewrite this as

$$\mathcal{F}_{S^3} = \frac{N^2}{L^3} \frac{\epsilon^{3A}}{k} \arccosh \frac{n}{2}.\quad (3.29)$$
Finally, following the arguments in [4], at fixed $n$ the type IIB supergravity approximation should be valid in the large $N$ limit since higher derivative corrections will be suppressed by terms of order $1/\sqrt{N}$.

4 $\mathcal{N} = 1^*$ equal mass, SO(3) invariant model

This model is obtained from the 10-scalar model by setting $z^2 = z^3 = -z^4$, or equivalently $\alpha_1 = \alpha_2 = \alpha_3$ and $\phi_1 = \phi_2 = \phi_3$, as well as $\beta_1 = \beta_2 = 0$. This four-scalar model is parametrised by the two complex fields

$$z^1 = \tanh\left[\frac{1}{2}(3\alpha_1 + \varphi - 3i\phi_1 + i\phi_4)\right], \quad z^2 = \tanh\left[\frac{1}{2}(\alpha_1 - \varphi - i\phi_1 - i\phi_4)\right].$$

The integral of motion (3.7) for this truncation is given by

$$E = \frac{1}{L^3}e^{3A}\frac{1}{2}\left[-\tan(3\phi_1 - \phi_4) + 3\tan(\phi_1 + \phi_4)\right].$$

This model has two further sub-truncations as illustrated in figure 2, and in particular contains the known $\mathcal{N} = 1$ and $\mathcal{N} = 4$ AdS $4 \times \mathbb{R}$ S-fold solutions. Firstly, if we set $z^1 = -z^2$, equivalently, $\alpha_1 = \phi_1 = 0$, then we obtain a two-scalar SU(3) invariant model depending on $\varphi, \phi_4$ that overlaps\(^7\) with the truncation considered in the context of $\mathcal{N} = 1$ S-folds in section 4 of [10].

The $\mathcal{N} = 1$ AdS $4 \times \mathbb{R}$ S-fold solution is given (in conformal gauge) by

$$\varphi = \frac{\sqrt{5}}{2}r, \quad \phi_4 = \cos^{-1}\frac{\sqrt{5}}{6}, \quad e^A = \frac{5L}{6}, \quad \alpha_1 = \phi_1 = 0,$$

and we have $E = \frac{25\sqrt{5}}{108}$. There is another $\mathcal{N} = 1$ S-fold solution obtained from the symmetry (2.8), with opposite sign for $E$. The free energy of these solutions can be obtained from (3.29) and is given by

$$F_{S^4} = \frac{25\sqrt{5}}{108} \arccosh\frac{n}{2}N^2,$$

in agreement with [10].

On the other hand if we further set $z^2 = z^4$, or equivalently $\phi_1 = -\phi_4$, then we obtain a three-scalar SO(3) $\times$ SO(3) invariant model depending on $\alpha_1, \phi_1, \varphi$ that overlaps\(^8\) with the truncation considered in the context of $\mathcal{N} = 4$ S-folds in section 2 of [10]. The $\mathcal{N} = 4$ S-fold solution is given (in conformal gauge) by

$$\varphi = \frac{1}{\sqrt{2}}r, \quad \phi_1 = -\phi_4 = -\frac{1}{2}\cot^{-1}\sqrt{2}, \quad e^A = \frac{L}{\sqrt{2}}, \quad \alpha_1 = 0,$$

\(^7\)They consider a model with four scalars: $(\varphi, \chi, c, \omega)$. One should set $c = \omega = 0$ and then identify $\sin\phi_4 = \tanh\chi$ as well as $g = 2/L$.

\(^8\)They consider a model with five scalars: $(\varphi, \chi, \alpha, c, \omega)$. One should set $c = \omega = 0$ and then identify $\alpha_1 = \alpha$ and $\sin 4\phi_1 = -\tanh 4\chi$. We also note that setting $z^2 = \tilde{z}^2$ in the BPS equations (3.5) leads to an additional algebraic reality constraint. The compatibility of imposing this constraint with the BPS equations can be verified as in section 5 of [15] for a similar issue associated with the reality of the scalar fields $\beta_1, \beta_2$. 
and has $\mathcal{E} = \frac{1}{2}$. Again there is another $\mathcal{N} = 4$ S-fold solution obtained from the symmetry (2.8), with opposite sign for $E$. From (3.29) the free energy of these solutions is given by

$$F_{S^3} = \frac{1}{2} \text{arccosh} \frac{n}{2} N^2,$$

(4.6)

in agreement with [4, 10].

The model also contains a single periodic $\text{AdS}_4 \times \mathbb{R}$ solution that was found numerically in [15] which has $\mathcal{E} = 0$. In this solution the warp factor $e^A$ and all the scalar fields, including $\varphi$, are periodic in the radial direction. Thus, it can immediately be compactified to give an $\text{AdS}_5 \times S^4$ solution of $D = 5$ supergravity and then uplifted to an $\text{AdS}_4 \times S^1 \times S^5$ solution of type IIB using the results of appendix A. From the numerical results we can calculate the free energy (3.28) and we find

$$F_{S^3} \approx q \times 1.90107 N^2,$$

(4.7)

where $q$ is the number of periods over which we have compactified.

The periodic solution was found as a limiting case of a class of Janus solutions in [15]. The focus in [15] was Janus solutions that approach the $\mathcal{N} = 4$ SYM vacuum with the same value of $\varphi$ on either side of the interface, corresponding to the same value of $\tau$ of the $\mathcal{N} = 4$ SYM on either side of the interface. It is straightforward to generalise these Janus solutions to allow $\varphi$ on either side of the interface. As already noted, taking limits of these solutions leads to new families of $\text{AdS}_4 \times \mathbb{R}$ solutions with $\varphi$ an LPP function of the radial coordinate, $r$, which parametrises $\mathbb{R}$. Before summarising these new solutions, all found numerically, we discuss how some of the new family of solutions can also be seen by perturbing the $\text{AdS}_4 \times \mathbb{R}$ solution associated with the $\mathcal{N} = 1$ S-fold solution.

### 4.1 Periodic perturbation about the $\mathcal{N} = 1$ S-fold

Within the $\mathcal{N} = 1^*$ equal mass model, we consider linearised perturbations of the BPS equations about the $\text{AdS}_4 \times \mathbb{R}$ solution (4.3), associated with the $\mathcal{N} = 1$ S-fold. There are zero modes associated with shifts of $\varphi$, $A$ and there is also a freedom to shift the coordinate $r$. There are two linearised modes that depend exponentially on $r$. Of most interest is that there is also a linearised periodic mode of the form

$$\delta \alpha_1 = \sin \frac{\sqrt{5}r}{3}, \quad \delta \varphi_1 = -\sqrt{5} \cos \frac{\sqrt{5}r}{3}.$$

(4.8)

With a little effort we can use this periodic mode to construct a perturbative expansion in a parameter $\epsilon$, that takes the form

$$\alpha_1 = \sum_{m,p=1}^{\infty} a^{(\alpha_1)}_{m,p} \epsilon^m \sin pKr, \quad \phi_1 = \phi_1^m(\epsilon) + \sum_{m,p=1}^{\infty} a^{(\phi_1)}_{m,p} \epsilon^m \cos pKr,$$

$$\phi_4 = \phi_4^m(\epsilon) + \sum_{m,p=1}^{\infty} a^{(\phi_4)}_{m,p} \epsilon^m \cos pKr, \quad \varphi = k(\epsilon) r + \sum_{m,p=1}^{\infty} a^{(\varphi)}_{m,p} \epsilon^m \sin pKr,$$

$$A = A^m(\epsilon) + \sum_{m,p=1}^{\infty} a^{(A)}_{m,p} \epsilon^m \cos pKr,$$

(4.9)
where all functions are periodic in the radial direction with period $\Delta r \equiv \frac{2\pi}{K}$, with $\varphi$ having an extra linear piece, and hence an LPP function, exactly as in (3.13)–(3.15). The wavenumber $K$ is itself given by the following series in $\epsilon$:

$$K \equiv \frac{2\pi}{\Delta r} = \frac{\sqrt{5}}{3} - \frac{184\sqrt{5}}{13} \epsilon^2 - \frac{2155938\sqrt{5}}{2197} \epsilon^4 - \frac{1193970682204}{1856465\sqrt{5}} \epsilon^6 + \cdots,$$

(4.10)

which we notice is decreasing as we move away from the $\mathcal{N} = 1$ S-fold solution. Interestingly, we notice that $\alpha_1$ has vanishing zero mode in this expansion, while the zero modes of the remaining periodic functions are explicitly given by

$$\phi_{1m}^{zm} = -5\sqrt{5}\epsilon^2 - \frac{9431\sqrt{5}}{26} \epsilon^4 - \frac{626904259}{26364\sqrt{5}} \epsilon^6 + \cdots,$$

$$\phi_{4m}^{zm} = \cos^{-1} \sqrt{\frac{5}{6}} - \sqrt{5e^2} - \frac{61645\sqrt{5}}{676} \epsilon^4 - \frac{110249429617}{1713660\sqrt{5}} \epsilon^6 + \cdots,$$

$$A_{zm} = \log \frac{5L}{6} - 3\epsilon^2 - \frac{102177}{338} \epsilon^4 - \frac{60279560187}{1428050} \epsilon^6 + \cdots.$$

(4.11)

In addition the slope of $\varphi$ takes the form

$$k = \frac{\sqrt{5}}{2} - \frac{9\sqrt{5}}{2} \epsilon^2 - \frac{513855\sqrt{5}}{1352} \epsilon^4 - \frac{295876107351}{1142440\sqrt{5}} \epsilon^6 + \cdots.$$

(4.12)

Furthermore we also have $\Delta \varphi \equiv k \Delta r$ is given by

$$\Delta \varphi = 3\pi + \frac{1305\pi}{13} \epsilon^2 + \frac{95032143\pi}{8788} \epsilon^4 + \frac{1189303785571\pi}{7425860} \epsilon^6 + \cdots.$$

(4.13)

The integral of motion (4.2) is given by

$$E = \frac{25\sqrt{5}}{108} \left(1 - 6\epsilon^2 - \frac{14598}{169} \epsilon^4 - \frac{1590041883}{142805} \epsilon^6 + \cdots\right)^{1/2}.$$

(4.14)

One finds that all of the expansion parameters $a_{m,p}^{(\epsilon)}$ appearing in (4.9) are only non-zero when $m + p$ is even. This implies the following property of the perturbative solution under a half period shift in the radial coordinate. Specifically, let $\Psi = \{A, \alpha_1, \phi_1, \phi_4\}$ denote the periodic functions so that the whole solution is specified by $\Psi(\epsilon, r)$ and $\varphi(\epsilon, r)$. We then find

$$\Psi(\epsilon, r + \pi/K) = \Psi(-\epsilon, r), \quad \varphi(\epsilon, r + \pi/K) = \varphi(-\epsilon, r) + \text{constant},$$

(4.15)

where the constant can be removed by (2.11). This means that changing the sign of $\epsilon$ gives, essentially, the same solution (i.e. up to a shift in the radial direction plus a shift of $\varphi$).
Finally, after uplifting to type IIB, using the results of appendix A, and carrying out the S-fold procedure, as described in section 3.3, we obtain new S-folds of type IIB provided that we can solve (3.23). The free energy for the S-folded solutions can then be obtained from (3.28) and is given by

$$F_{S^3} = \frac{25\sqrt{5}}{108} \left( 1 - \frac{1305}{13} \epsilon^4 - \frac{26414316}{13^3} \epsilon^6 + \ldots \right) \text{arccosh} \frac{n}{2} N^2. \tag{4.16}$$

To solve (3.23) we first note that

$$2 \cosh \frac{3\pi}{2} \sim 12391.6.$$ Thus, the smallest value of $n$ that can be reached in (3.23) is $n = 12392$, which occurs for $q = 1$ and $\epsilon \sim 0.0003$. There are additional branches of solutions, labelled by $q$, which, for a given $n$, have smaller values of $\epsilon$. Thus, we can find S-fold solutions with arbitrarily small $\epsilon$. We also note that while these AdS$_4 \times \mathbb{R}$ solutions are perturbatively connected with the $\mathcal{N} = 1$ AdS$_4 \times \mathbb{R}$ S-fold solution, they are not as S-folds of type IIB string theory. This is clear when we recall that for the latter we can solve (3.23) for any $n \geq 3$ by suitably adjusting the period $\Delta r$ over which we S-fold, while for the perturbative solutions, as just noted, we have $n \geq 12392$.

The $\mathcal{N} = 1^*$ equal mass, SO(3) invariant truncation we are considering also contains the known $\mathcal{N} = 4$ AdS$_4 \times \mathbb{R}$ S-fold solution (4.5). If we consider the linearised perturbations of the BPS equations about this solution we again find zero modes associated with shifts of $\varphi$, $A$, and there is also a freedom to shift the coordinate $r$. The remaining modes all depend exponentially on the radial coordinate. In particular, there is no longer a linearised periodic mode and this feature will manifest itself in the family of new solutions we discuss in the next section.

### 4.2 New S-fold solutions

The new AdS$_4 \times \mathbb{R}$ solutions, with $\varphi$ a LPP function, can be constructed as limiting cases of Janus solutions. A convenient way to numerically solve the BPS equations (3.3)–(3.5) is to set initial conditions for the scalar fields at a turning point of the metric warp function, $A$, which corresponds to $\text{Re}(B_r) = 0$ along with the values of the scalar fields at the turning points. Some general comments concerning this procedure were made in sections 5 and 6 of [15].

In more detail we consider Janus solutions with the turning point of $A$ located at $r = r_{tp}$. Since the BPS equations are unchanged by shifting the radial coordinate by a constant, we can take $r_{tp} = 0$. We can also use the shift symmetry (2.11) to choose $\varphi(r_{tp}) = 0$. We can then focus on solutions that are invariant under the $\mathbb{Z}_2$ symmetry, obtained by combining (2.8) and (3.6),

$$r \rightarrow -r, \quad z^A \rightarrow -z^A, \quad \xi \rightarrow -\xi + \pi. \tag{4.17}$$

If we relax the condition that the initial data is invariant under the $\mathbb{Z}_2$ symmetry, then we do not find any LPP solutions of the type we are interested in for constructing S-folds. Instead we find some interesting “one-sided” Janus solutions that we discuss in section 6. We also note that the general periodic perturbative solution (4.9) did not assume invariance under the $\mathbb{Z}_2$ symmetry, yet it is in fact invariant.
This implies that $\phi_1$, $\phi_4$ are even functions of $r$ and $\alpha_i$, $\varphi$ are odd functions. In particular, at the turning point we can take $\alpha_i(r_{\text{tp}}) = 0$ as part of our initial value data. For the SO(3) invariant model, these Janus solutions are therefore fixed by the values of $\phi_1(r_{\text{tp}})$ and $\phi_4(r_{\text{tp}})$. By suitably tuning the values of the scalar field at the turning points we are able to construct the limiting cases of solutions associated with the S-folds.

The space of solutions that we have found in this way is summarised by the coloured curve in figure 3, with the colour giving the value of $|\mathcal{E}|$, given by (4.2). If one starts with turning point data that lies anywhere within the curve, one obtains a Janus solution of $\mathcal{N} = 4$ SYM theory with fermion and boson masses and a coupling constant that varies as one crosses the interface. For example, the Janus solution depicted in figure 1 corresponds to the black cross inside the curve in figure 3. On the other hand if one starts outside the curve then one finds that the solution becomes singular on both sides of the interface as in the solutions discussed in [15], for example.

Observe that the figure is symmetric under changing the signs of both $\phi_1(r_{\text{tp}})$ and $\phi_4(r_{\text{tp}})$, as a result of the symmetry (2.8). The associated AdS$_4 \times \mathbb{R}$ solutions obtained by this symmetry, which is a discrete $R$-symmetry combined with an $S$-duality transformation for the associated Janus solutions, are physically equivalent. The value of $\mathcal{E}$ is positive for the upper part of the curve between the two red dots and negative for the lower part. We next point out that the blue dots correspond to the two $\mathcal{N} = 1$ AdS$_4 \times \mathbb{R}$ S-fold solutions, with $\varphi$ a linear function of $r$, as in (4.3). The red dots correspond to the fully periodic

---

**Figure 3.** Turning point initial data for the AdS$_4 \times \mathbb{R}$ solutions of the $\mathcal{N} = 1^*$ equal mass SO(3) invariant model. Red dots correspond to the exactly periodic solution, blue dots correspond to the $\mathcal{N} = 1$ linear dilaton solutions, green dots to the $\mathcal{N} = 4$ linear dilaton solutions and green squares to the bounce solutions. The remaining points correspond to AdS$_4 \times \mathbb{R}$ solutions with $\varphi$ a LPP function of $r$. All points inside the curve correspond to Janus solutions of $\mathcal{N} = 4$ SYM theory (the black cross is the Janus solution in figure 1), while points outside the curve have singularities. Points on the curve with the same colour represent the same solution, up to shifts of $\varphi$ and the discrete symmetry (2.8).
AdS$_4 \times \mathbb{R}$ solution found in [15]. We will come back to the green dots and squares in a moment. The remaining points on the curve all correspond to AdS$_4 \times \mathbb{R}$ solutions with $\varphi$ an LPP function of $r$. Also, if one starts at the $\mathcal{N} = 1$ S-fold solution at the top of the curve, then one can match on to the perturbative family of solutions that we constructed in the previous subsection and there is a similar story for the $\mathcal{N} = 1$ S-fold solution at the bottom of the curve.

Points on the curve with the same colour have the same value of $|\mathcal{E}|$ and represent, essentially, the same solution, up to dilaton shifts (2.11) and the discrete symmetry (2.8) if $\mathcal{E}$ has the opposite sign. Indeed if we move to the right from the blue dot at the top all the way to the red dot at the right, the LPP solutions (all of which have $\mathcal{E}$ positive) are essentially the same as those as one moves to the left; although the turning point data at $r = r_{tp}$ is different, the data of one of the solutions at $r = r_{tp}$ agrees with the turning point data of the other solution at $r = r_{tp} + \Delta r/2$, after making a suitable shift of $\varphi$ using (2.11). One can explicitly check this feature analytically for the perturbative solution (4.9). We also note that this feature is consistent with the fact that there is just a single periodic solution which has the property that if one uses (2.11) to have no zero mode for $\varphi$, then the solution is invariant under a half period shift combined with a $Z_2$ symmetry transformation (2.8).

We now return to the green dots and squares in figure 3. The green dots, located at $|\mathcal{E}| = 1/2$ represent the $\mathcal{N} = 4$ linear dilaton solutions given in (4.5), while the green squares represent “bounce” solutions that involve those solutions, as we now explain. We first consider the limiting class of the LPP solutions as we move along the coloured curve in figure 3 towards the upper green dot to the left. To illustrate, in the left panel of figure 4 we have displayed the behaviour of one of the periodic functions, $\phi_1(r)$, as one approaches the critical initial data associated with the green dot, which has $\phi_1(r_{tp}) = -1/2 \cot^{-1} \sqrt{2} \sim -0.308$. The figure shows that in this limit, the solution simply degenerates into the $\mathcal{N} = 4$ linear dilaton solution (4.5) for all values of $r$. In the right panel of figure 4 we have also displayed the approach to the upper green square to the right. In this case the solution develops a region that approaches the $\mathcal{N} = 4$ linear dilaton solution (4.5) as one moves away from $r = 0$ in either direction. Exactly at the initial values associated with the green square the solution will no longer be an LPP solution but degenerates into a “bounce solution” which approaches the $\mathcal{N} = 4$ linear dilaton solution (4.5) at both $\bar{r}/L \to \pm \infty$, with a kink in the middle. We also see that these degenerations of the LPP solutions split the whole family of solutions into two branches of LPP solutions: one that includes the perturbative solutions built using the $\mathcal{N} = 1$ linear dilaton solutions and another that contains the periodic solution.

In order to obtain S-fold solutions of type IIB string theory we also need to impose the quantisation condition (3.23). In figure 5 we have plotted some of these discrete solutions as well as $F_{S^3}$ given in (3.28). The discrete set of vertical points coloured blue and green correspond to the $\mathcal{N} = 1$ and $\mathcal{N} = 4$ S-fold solutions with linear dilatons, respectively, and $n$ increasing from 3 to infinity as one goes up; for these S-folds we can obtain all values $n \geq 3$ by suitably adjusting the period $\Delta r$ over which we S-fold. The red dots correspond to the periodic solution for different values of the numbers of period, $q$, that are used in
Figure 4. Family of LPP solutions for the $\mathcal{N} = 1^*$ equal mass SO(3) invariant model with turning point data illustrating the approach to the green dots and squares as in figure 3, with $|\mathcal{E}| = 1/2$. The figures display just the periodic behaviour of $\phi_1$ for clarity and just one period. The left panel shows that the limiting solutions associated with the green dots degenerate into the $\mathcal{N} = 4$ linear dilaton solution, marked with a dashed green line. The right panel shows the limiting solution associated with the green square becomes a bounce solution which approaches the $\mathcal{N} = 4$ linear dilaton solution, at both $\bar{r} \to \pm \infty$, with a kink in $\phi_1$ centred at $\bar{r} = 0$.

Figure 5. Plot of the discrete S-folded solutions and the associated free energy of the dual field theory, $\mathcal{F}_{S^3}$, for the $\mathcal{N} = 1^*$ equal mass SO(3) invariant model as in figure 3. The discrete points rapidly become indistinguishable from continuous lines. making the $S^1$ compactification. The remaining discrete points correspond to $\mathcal{N} = 1$ S-fold solutions with $\varphi$ an LPP function, for representative values of $q = 1, 2, 3$. Starting from the left, for a given $q$, we have $n = 3$ at the left and then rising to infinity as one approaches the bounce solution or the $\mathcal{N} = 4$ S-fold solution at $\mathcal{E} = 1/2$, where the free energy diverges. Moving further to the right the value of $n$ decreases from infinity down to a bounded value $[2 \cosh q 3 \pi]$, at the intersection with the $\mathcal{N} = 1$ solutions on the blue line, which can be deduced from the perturbative analysis (4.13).
5 5-scalar model, SU(2) invariant

This model is obtained from the 10-scalar model by setting $z^1 = -z^3$, $z^2 = -z^4$, or equivalently $\alpha_1 = \alpha_2 = 0$, $\phi_1 = \phi_2 = 0$, $\beta_2 = 0$. This model involves five scalar fields parametrised by

$$\beta_1, \ z^1 = \tanh \left[ \frac{1}{2} (\alpha_3 + \varphi - i\phi_3 + i\phi_4) \right], \ z^2 = \tanh \left[ \frac{1}{2} (\alpha_3 - \varphi - i\phi_3 - i\phi_4) \right].$$ (5.1)

In addition to the symmetry (2.8), this model is also invariant under the symmetry

$$\phi_3 \rightarrow -\phi_3, \quad \alpha_3 \rightarrow -\alpha_3,$$ (5.2)

with $\beta_1, \phi_4, \varphi$ unchanged, which is a remnant of the discrete transformations given in (2.10) for the 10-scalar truncation. This additional symmetry will clearly manifest itself in the set of solutions we construct. The integral of motion (3.7) for this truncation is now given by

$$E = \frac{1}{L^3} e^{3A}[-\tan(\phi_3 - \phi_4) + \tan(\phi_3 + \phi_4)].$$ (5.3)

If we further set $z^1 = -z^2$, equivalently, $\alpha_3 = \phi_3 = 0$, as well as $\beta_1 = 0$ then we obtain a two-scalar model depending on $\varphi, \phi_4$ that overlaps with the truncation considered in the context of $\mathcal{N} = 1$ S-folds in section 4 of [10], which we also discussed in the previous section. In particular the AdS$_4 \times \mathbb{R}$ solution associated with the $\mathcal{N} = 1$ S-folds is given by

$$\varphi = \frac{\sqrt{5}}{2} r, \quad \phi_4 = \cos^{-1} \sqrt{\frac{5}{6}}, \quad e^A = \frac{5L}{6}, \quad \beta_1 = \alpha_3 = \phi_3 = 0,$$ (5.4)

with $E = \frac{25\sqrt{5}}{108}$. There is another $\mathcal{N} = 1$ S-fold solution that can be obtained from the symmetry (2.8), with opposite sign for $E$.

On the other hand if we set $z^2 = \bar{z}^2$ or equivalently $\phi_3 = -\phi_4$ then we obtain a four-scalar model depending on $\phi_3, \alpha_3, \varphi, \beta_1$ that overlaps with the truncation considered in the context of $\mathcal{N} = 2$ S-folds in section 3 of [10]. Also note that after utilising the symmetry (5.2) we can also truncate to a 4-scalar model by taking $z^1 = \bar{z}^1$, or equivalently $\phi_3 = +\phi_4$. The $\mathcal{N} = 2$ S-fold solution, with $\phi_3 = -\phi_4$, can be written

$$\varphi = r, \quad \phi_3 = -\phi_4 = -\frac{\pi}{8}, \quad \beta_1 = -\frac{1}{12} \log 2, \quad e^A = \frac{L}{2^{1/3}}, \quad \alpha_3 = 0,$$ (5.5)

with $E = \frac{1}{2}$. After using the symmetries (2.8) and (5.2) there are now a total of four $\mathcal{N} = 2$ AdS$_4 \times \mathbb{R}$ S-fold solutions with $\varphi$ linear in $r$. From (3.29) the free energy of these solutions is given by

$$F_{g^3} = \frac{1}{2} \text{arccosh} \frac{n}{2} N^2,$$ (5.6)

in agreement with [10].

---

\textsuperscript{10}They consider a model with seven scalars: $(\varphi, \chi, \alpha, \lambda, c, \omega, \psi)$. One should set $c = \omega = \psi = 0$ and then identify $\alpha = \beta_1$, $\lambda = \alpha_3$, $\sin 2\phi_3 = -\tanh 2\chi$ as well as $g = 2/L$. 
Finally, if we set $z^1 = z^2$ or equivalently $\phi_4 = \varphi = 0$ then we obtain the $\mathcal{N} = 1^*$ one-mass truncation used in [15], which contains three scalars $\beta_1, \phi_3, \alpha_3$ and retains the symmetry (5.2). This truncation also contains two LS AdS$_5$ fixed point solutions, LS$^{\pm}$, which are related by (5.2) and given by

$$
\beta_1 = -\frac{1}{6} \log 2, \quad \phi_3 = \pm \frac{\pi}{6}, \quad \alpha_3 = 0, \quad \tilde{L} = \frac{3}{2^{5/3}} L,
$$

where $\tilde{L}$ is the radius of the AdS$_5$.

### 5.1 Periodic perturbation about the $\mathcal{N} = 1$ S-fold

Much as in the last section, within the 5-scalar truncation we can build a perturbative solution about the $\mathcal{N} = 1$ S-fold solution given in (5.4). The key point is that there is now a periodic linearised perturbation of the form

$$
\delta \alpha_3 = \sin \frac{\sqrt{5} \varphi}{3}, \quad \delta \phi_3 = -\sqrt{5} \cos \frac{\sqrt{5} \varphi}{3}.
$$

With some effort we can use this to construct a perturbative expansion in a parameter $\epsilon$, that takes the form

$$
\begin{align*}
\alpha_3 &= \sum_{m,p \in \text{odd}} a^{(\alpha_3)}_{m,p} \epsilon^m \sin p K r, \\
\phi_3 &= \sum_{m,p \in \text{odd}} a^{(\phi_3)}_{m,p} \epsilon^m \cos p K r, \\
\phi_4 &= \phi_4^{zm}(\epsilon) + \sum_{m,p \in \text{even}} a^{(\phi_4)}_{m,p} \epsilon^m \cos p K r, \\
\varphi &= k(\epsilon) r + \sum_{m,p \in \text{even}} a^{(\varphi)}_{m,p} \epsilon^m \sin p K r, \\
\beta_1 &= \beta_1^{zm}(\epsilon) + \sum_{m,p \in \text{even}} a^{(\beta_1)}_{m,p} \epsilon^m \cos p K r, \\
A &= A^{zm}(\epsilon) + \sum_{m,p \in \text{even}} a^{(A)}_{m,p} \epsilon^m \cos p K r,
\end{align*}
$$

where the sums over odd integers start from 1 and the sums over even integers start from 2. All functions, except $\varphi$ are periodic in the radial direction with period $\Delta r = \frac{2\pi}{K}$, with $\varphi$ an LPP function, exactly as in (3.13)–(3.15). The wavenumber $K$ is itself given by the following series in $\epsilon$:

$$
K \equiv \frac{2\pi}{\Delta r} = \frac{\sqrt{5}}{3} - \frac{292\sqrt{5}}{117} \epsilon^2 - \frac{3316328\sqrt{5}}{59319} \epsilon^4 - \frac{241179878834}{30074733\sqrt{5}} \epsilon^6 + \cdots,
$$

which we notice is decreasing as we move away from the $\mathcal{N} = 1$ S-fold solution.

Notice that both $\alpha_3$ and $\phi_3$ have vanishing zero mode in this expansion. The zero modes of the remaining periodic functions are explicitly given by

$$
\begin{align*}
\phi_4^{zm} &= \cos^{-1}\left(\sqrt[3]{\frac{5}{6}}\right) - \frac{\sqrt{5}}{3} \epsilon^2 - \frac{4861\sqrt{5}}{6084} \epsilon^4 - \frac{185672641\sqrt{5}}{9253764} \epsilon^6 + \cdots, \\
\beta_1^{zm} &= -\frac{2}{3} \epsilon^2 - \frac{755}{78} \epsilon^4 - \frac{5171099}{19773} \epsilon^6 + \cdots, \\
A^{zm} &= \log\left(\frac{5L}{6}\right) - \epsilon^2 - \frac{10241}{3042} \epsilon^4 - \frac{663866873}{4626882} \epsilon^6 + \cdots.
\end{align*}
$$
In addition the slope of $\varphi$ takes the form
\[ k = \sqrt{\frac{5}{2}} - \frac{3\sqrt{5}}{2} \epsilon^2 - \frac{311\sqrt{5}}{1352} \epsilon^4 - \frac{19753429\sqrt{5}}{228488} \epsilon^6 + \cdots. \] (5.12)

Furthermore, we also have $\Delta \varphi \equiv k \Delta r$ is given by
\[ \Delta \varphi = 3\pi + \frac{175\pi}{13} \epsilon^2 + \frac{5295375\pi}{8788} \epsilon^4 + \frac{153607091549\pi}{7425860} \epsilon^6 + \cdots. \] (5.13)

The integral of motion (5.3) is given by
\[ E = \frac{25\sqrt{5}}{108} \left( 1 - 175\epsilon^2 + 4598 \frac{\epsilon^4}{507} + 96057473 \frac{\epsilon^6}{771147} + \cdots \right). \] (5.14)

We now write the periodic functions collectively as $\Psi_1 = \{ A, \phi_4, \beta_1 \}$ and $\Psi_2 = \{ \alpha_3, \phi_3 \}$ so that the whole solution is specified by $\Psi_1(\epsilon, r)$, $\Psi_2(\epsilon, r)$ and $\varphi(\epsilon, r)$. We then find
\[ \begin{align*}
\Psi_1(\epsilon, r + \pi/K) &= \Psi_1(-\epsilon, r) = +\Psi_1(\epsilon, r), \\
\Psi_2(\epsilon, r + \pi/K) &= \Psi_2(-\epsilon, r) = -\Psi_2(\epsilon, r), \\
\varphi(\epsilon, r + \pi/K) &= \varphi(-\epsilon, r) + \text{constant},
\end{align*} \] (5.15)

where the constant can be removed by (2.11) and we note that the last equalities in the first two lines are associated with the symmetry (5.2).

After uplifting to type IIB and carrying out the S-fold procedure as described in section 3.3, we obtain new S-folds of type IIB provided that we can solve (3.23). This can be done as in the discussion following (4.16) and, in particular, the smallest value of $n$ that can be reached in (3.23) is $n = 12392$, which occurs for $q = 1$ and $\epsilon \sim 0.0008$. The free energy for the S-folded solutions can be obtained from (3.28) and is given by
\[ \mathcal{F}_{S^3} = \frac{25\sqrt{5}}{108} \left( 1 - \frac{175}{39} \epsilon^4 - \frac{13887100}{39^3} \epsilon^6 + \cdots \right) \arccosh \frac{n}{2} N^2. \] (5.16)

This truncation also contains the known $\text{AdS}_4 \times \mathbb{R} \mathcal{N} = 2$ S-fold solutions, but there is no longer a linearised periodic mode within this truncation in which to build an analogous solution. This is similar to the known $\text{AdS}_4 \times \mathbb{R} \mathcal{N} = 4$ S-fold solutions in the $\text{SO}(3)$ invariant truncation that we considered in the previous section.

### 5.2 New S-fold solutions

The new $\text{AdS}_4 \times \mathbb{R}$ solutions, with $\varphi$ a LPP function, can be constructed as limiting cases of Janus solutions, much as in the last section. We again start by constructing Janus solutions with turning point of $A$ at $r = r_{tp}$, with $r_{tp} = 0$. We can use the shift symmetry (2.11) to choose $\varphi(r_{tp}) = 0$. We then focus\footnote{As in the previous section, if we relax the condition that the initial data is invariant under the $\mathbb{Z}_2$ symmetry, then we only find limiting solutions that are in the “one-sided” Janus class discussed in section 6. We also note that the perturbative solution (5.9) is invariant under this symmetry.} on solutions that are invariant under the $\mathbb{Z}_2$ symmetry, obtained by combining (2.8) and (3.6),
\[ \begin{align*}
r &\to -r, \\
z^A &\to -z^A, \\
\xi &\to -\xi + \pi.
\end{align*} \] (5.17)
Figure 6. Turning point initial data for the $\text{AdS}_4 \times \mathbb{R}$ solutions of the 5-scalar SU(2) invariant model. The blue dots correspond to the $\mathcal{N} = 1$ linear dilaton solutions while the green dots correspond to the $\mathcal{N} = 2$ linear dilaton solutions, as well as associated soliton solutions. The red dots correspond to the two LS $\text{AdS}_5$ solutions, $\text{LS}^\pm$. The remaining points on the solid lines correspond to $\text{AdS}_4 \times \mathbb{R}$ solutions with $\varphi$ a LPP function of $r$, with the same colour representing the same physical solution. All points inside the curve correspond to Janus solutions of $\mathcal{N} = 4$ SYM theory while points outside the curve have singularities. The dashed lines correspond to an LS$^\pm$ to LS$^\pm$ Janus solution.

This implies that $\phi_3, \phi_4$ are even functions of $r$ and $\alpha_3, \varphi$ are odd functions. Thus, we again take $\alpha_3(r_{tp}) = 0$ as part of our initial value data for the solutions. From (3.3)—(3.5), and as explained in section 5 of [15], the solutions are now specified by the values of $\phi_3(r_{tp})$ and $\phi_4(r_{tp})$, with the value of $\beta_1(r_{tp})$ fixed by this data. By suitably tuning the values of the scalar field at the turning points we are able to construct the limiting cases of solutions associated with the S-folds.

The space of solutions we have found in this way is summarised by the curve shown in figure 6. If one starts with turning point data that lies anywhere within the curve, one obtains a Janus solution of $\mathcal{N} = 4$ SYM theory with fermion and boson masses and a coupling constant that varies as one crosses the interface. On the other hand if one starts outside the curve then one finds that the solution becomes singular on both sides of the interface.

Observe that the figure is symmetric under changing the signs of either $\phi_3(r_{tp})$ or $\phi_4(r_{tp})$. This is a result of the symmetries (2.8) and (5.2). The associated $\text{AdS}_4 \times \mathbb{R}$ solutions obtained using these symmetries, which for the Janus solutions are a combination of a discrete $R$-symmetry and an $S$-duality transformation (in the case of (2.8)), are physically equivalent. The value of $\mathcal{E}$ is positive for the upper part of the curve and negative for the lower part. We next point out that the blue dots correspond to the $\mathcal{N} = 1 \text{ AdS}_4 \times \mathbb{R}$ S-fold solutions which have $\varphi$ a linear function of $r$. The green dots represent the $\mathcal{N} = 2 \text{ AdS}_4 \times \mathbb{R}$ S-fold solutions as well as associated “soliton” solutions that we discuss further below. The remaining points on the coloured, solid lines all correspond to $\text{AdS}_4 \times \mathbb{R}$ solutions with $\varphi$ an LPP function of $r$. Also, if one starts at the $\mathcal{N} = 1$ S-fold solution at the top of the
Figure 7. Limiting families of solutions for the 5-scalar SU(2) invariant model, with just the periodic behaviour of $\phi_3$ displayed for clarity. The left panel illustrates the approach to the green dots in figure 3, along the coloured curve; one finds that the solution will approach the $\mathcal{N}=2$ linear dilaton solution associated with the upper green dashed line for all $\bar{r}$. In the right panel we display a different limiting solution, obtained by fixing $\phi_3(0)=0$, which degenerates into a soliton solution that approaches one $\mathcal{N}=2$ linear dilaton solution, at $\bar{r} \to -\infty$ and another $\mathcal{N}=2$ linear dilaton solution at $\bar{r} \to \infty$ with opposite sign of $\phi_3$ (related by (5.2)).

Points on the solid curve with the same colour represent, essentially, the same LPP solution, up to dilaton shifts and possible discrete symmetries. Moving from the right of the blue dot at the top all the way to the green dot at the right one finds LPP solutions that are essentially the same as those as one moves to the left; although the turning point data at $r = r_{tp}$ is different, the data of one of the solutions at $r = r_{tp}$ agrees with the turning point data of the other solution at $r = r_{tp} + \Delta r/2$, after making a suitable shift of $\phi$ using (2.11). Note that the two sets of turning point data are also related by (5.2). One can explicitly check these features analytically for the perturbative solution (5.9).

In the limit of approaching the green dots in figure 6 along the solid curve, the LPP solutions degenerate into the $\text{AdS}_4 \times \mathbb{R} \mathcal{N}=2$ S-fold solutions as illustrated in the left panel in figure 7 for one of the periodic functions, $\phi_3(r)$. As one approaches the critical initial data associated with the green dot which has $\phi_3 = \frac{\pi}{2} \sim 0.39$, the solution degenerates into the $\mathcal{N}=2$ S-fold solution, with the region around $\bar{r} = 0$ extending out all the way to infinity. Interestingly, essentially using the same family of solutions, one can construct another limiting solution which is a kind of “soliton” solution that approaches one of the $\text{AdS}_4 \times \mathbb{R} \mathcal{N}=2$ S-fold solutions as $\bar{r} \to -\infty$ and a different $\text{AdS}_4 \times \mathbb{R} \mathcal{N}=2$ S-fold solution, related by flipping the sign of $\phi_3$, as $\bar{r} \to \infty$. This limiting solution is illustrated in the right panel of figure 7.

We next turn to the remaining points in figure 6. The red dots are the two LS AdS$_5$ fixed points given in (5.7), which we refer to as LS$^\pm$. Moving along the class of Janus solutions on the horizontal axis towards the red dots at the right, say, one finds that the Janus solutions degenerate into three components; a Poincaré invariant RG flow solution that starts off at the AdS$_5$ vacuum and then approaches the LS$^+$ AdS$_5$ fixed point, the LS$^+$ fixed point solution itself and then another Poincaré invariant RG flow solution going
between LS$^+$ and the AdS$_5$ vacuum. The dashed curves correspond to another interesting degeneration of the Janus solutions. As one approaches the dashed curve on the right side of the figure one again finds three components: there is the same two Poincaré invariant components on the outside and the middle component is now an LS Janus solution that moves between LS$^+$ and LS$^+$ on either side of the interface, with $\varphi$ linear in $\bar{r}$. There is similar behaviour as one approaches the red dot or the dashed line on the left side of the figure with LS$^-$ replacing LS$^+$.

To obtain S-fold solutions of type IIB string theory we also need to impose the quantisation condition (3.23). In figure 8 we have plotted some of these discrete solutions as well as $\mathcal{F}_{s^3}$ given in (3.28). The discrete set of vertical points coloured blue and green correspond to the $\mathcal{N} = 1$ and $\mathcal{N} = 2$ S-fold solutions with linear dilatons, respectively, and $n$ increasing from 3 to infinity as one goes up. The remaining discrete points correspond to $\mathcal{N} = 1$ S-fold solutions with $\varphi$ an LPP function, for representative values of $q = 1, 2$. Starting from the right at the blue dots, for a given $q$, we have $n$ starting from $[2 \cosh q3\pi]$, which can be deduced from the perturbative analysis (5.13), and then rising to infinity as one approaches the $\mathcal{N} = 2$ S-fold solution at $\mathcal{E} = 1/2$, where the free energy diverges.

6 One-sided Janus solutions

In this section we discuss a novel class of $D = 5$ solutions within the ansatz (3.1), that at one end of $\mathbb{R}$ approach the AdS$_5$ vacuum, while at the other end approach an AdS$_4 \times \mathbb{R}$ solution with the $D = 5$ dilaton, $\varphi$, either a linear function or an LPP function of $r$. We can also construct solutions that approach the periodic AdS$_4 \times \mathbb{R}$ solution at the other end. We refer to these solutions as “one-sided Janus” solutions. In contrast to other one sided Janus solutions that have been previously constructed, for example in [15, 25, 29, 30], remarkably these new solutions are free from singularities.

6.1 An analytic solution preserving $\mathcal{N} = 4$ supersymmetry

We first consider an analytic solution that lies within the SO(3)$\times$SO(3) invariant truncation that involves 3 scalar fields, $\phi_1 = \phi_2 = \phi_3 = -\phi_4$, $\alpha_1 = \alpha_2 = \alpha_3$ and $\varphi$. 

---

**Figure 8.** Plot of the discrete S-folded solutions and the associated free energy of the dual field theory, $\mathcal{F}_{s^3}$, for the 5-scalar SU(2) invariant model as in figure 6. The discrete points rapidly become indistinguishable from a continuous line.
Using the proper distance gauge with radial coordinate \( \tilde{r} \), we find the following solution

\[
\tan 4\phi_1 = -\frac{2\sqrt{2} e^{-3\varphi/L}}{(1 + e^{-2\varphi/L})^{3/2}} , \quad \cosh 4\alpha_1 = \frac{1 + \frac{2e^{-4\varphi/L}}{(1+e^{-2\varphi/L})^2}}{\sqrt{1 + \frac{8e^{-6\varphi/L}}{(1+e^{-2\varphi/L})^2}}},
\]

\[e^{8\varphi-8\varphi(s)} = \frac{1 + 3e^{-2\varphi/L}}{(1 + e^{-2\varphi/L})^3 (1 + 3e^{-4\varphi/L})}, \quad e^{A} = \frac{Le^{4\varphi/L} \sqrt{1 + e^{-2\varphi/L}}}{\sqrt{2}}. \quad (6.1)
\]

For these solutions, in which the warp factor \( A \) does not have a turning point, we find that the integral of motion is given by \( E = \frac{1}{2} \). Recall that the \( \mathcal{N} = 4 \) S-fold solution with a linear dilaton given in (4.5) also had \( E = \frac{1}{2} \). In other words, taking the limit \( E \to \frac{1}{2} \) in the family of Janus solutions in this truncation can either give the \( \mathcal{N} = 4 \) S-fold solution or this new solution, which describes a one-sided Janus solution.

At the \( \tilde{r} \to +\infty \) end these solutions approach the AdS\(_5\) vacuum solution, dual to \( \mathcal{N} = 4 \) SYM theory. After shifting the radial coordinate \( \tilde{r} \to \tilde{r} - \frac{L}{\sqrt{2}} \log \frac{L}{\sqrt{2}} \), so we can easily compare with [15], we find that as \( \tilde{r} \to \infty \) we have the asymptotic expansion

\[
\phi_1 = -\frac{L^3}{4} e^{-3\varphi/L} + \ldots , \quad \alpha_1 = \frac{L^2}{4} e^{-2\varphi/L} - \frac{L^4}{4} e^{-4\varphi/L} + \ldots ,
\]

\[\varphi = \varphi(s) - \frac{3L^4}{16} e^{-4\varphi/L} + \ldots , \quad A = \frac{\tilde{r}}{L} + \frac{L^2}{4} e^{-2\varphi/L} - \frac{L^4}{16} e^{-4\varphi/L} + \ldots . \quad (6.2)
\]

From the results given in [15] we can immediately deduce that all sources for the operators dual to the scalar fields vanish. Furthermore, we can also determine the one point functions. As explained in detail [15], and refined in appendix B, we can determine the one-point functions that are associated with \( \mathcal{N} = 4 \) SYM theory on flat spacetime\(^{12}\) with coordinates \((t,y)\); we find that the one-point functions having spatial dependence on one of the spatial directions, say \( y_3 \), with\(^{13}\)

\[L^2 \langle O_{\alpha_1} \rangle = \frac{N^2}{8\pi^2} \frac{1}{y_3^2} , \quad L \langle O_{\phi_1} \rangle = -\frac{N^2}{4\pi^2} \frac{1}{y_3^2} , \quad \langle O_{\varphi} \rangle = -\frac{3N^2}{8\pi^2} \frac{1}{y_3^2} , \quad (6.3)
\]

where we used (3.27). These expressions display the appropriate dependence on \( y_3 \) that is consistent with \( d = 3 \) conformal invariance with respect to the \((t,y_1,y_2)\) for dual operators of scaling dimension \( \Delta = 2, 3 \) and 4, respectively.

At the other end, as \( \tilde{r} \to -\infty \), again after shifting \( \tilde{r} \to \tilde{r} - \frac{L}{\sqrt{2}} \log \frac{L}{\sqrt{2}} \), the asymptotic expansion is given by

\[
\phi_1 = -\frac{1}{4} \tan^{-1} \left(2\sqrt{2} \right) + \frac{1}{3\sqrt{2}L^2} e^{2\varphi/L} + \frac{1}{18\sqrt{2}L^3} e^{4\varphi/L} + \ldots , \quad \alpha_1 = \frac{1}{3L^2} e^{2\varphi/L} - \frac{4}{9L^4} e^{4\varphi/L} + \ldots ,
\]

\[\varphi = \frac{\tilde{r}}{L} + \varphi(s) - \log \frac{L}{\sqrt{2}} - \frac{2}{3L^2} e^{2\varphi/L} + \frac{5}{9L^4} e^{4\varphi/L} + \ldots , \quad A = \log \frac{L}{\sqrt{2}} + \frac{1}{L^2} e^{2\varphi/L} - \frac{1}{L^4} e^{4\varphi/L} + \ldots . \quad (6.4)
\]

---

\(^{12}\)As opposed to AdS\(_4\) to which it is related by a Weyl transformation. We also note that the analysis in [15] assumed \( \varphi(s) = 0 \) which can be achieved by a dilaton shift.

\(^{13}\)Note that the operators have not been canonically normalised, which explains the factors of \( L \) appearing on the left hand side.
This shows that the solution at this end is precisely approaching the $\mathcal{N} = 4$ AdS$_4 \times \mathbb{R}^4$ S-fold solution with $\varphi$ a linear function of $r$, which was given in (4.5).

The solution solves the BPS equations (3.3)–(3.5) and hence it preserves at least $\mathcal{N} = 1$ supersymmetry. However, since it is a solution that lies within the SO(3) $\times$ SO(3) invariant truncation it actually preserves $\mathcal{N} = 4$ supersymmetry. Furthermore, after uplifting the solution to type IIB, using the formulae in appendix A.2.2, we obtain a $D = 10$ metric of the form

$$ds^2 = f_2^2 ds_{\text{AdS}_4}^2 + f_1^2 d\Omega_2^2 + f_2^2 d\Omega_2^2 + ds^2(\Sigma), \quad (6.5)$$

where $d\Omega_2^2$ and $d\Omega_2^2$ are metrics on round two-spheres and $f_1, f_2$ and $f_4$ are functions of the coordinates on $\Sigma$. A full classification of such solutions which preserve $\mathcal{N} = 4$ supersymmetry can be found in [19, 20]. In appendix A.4 we explicitly show that our uplifted solution lies within this framework. In particular, the Riemann surface is taken to be an infinite strip with complex coordinate $w$

$$w = x + iv, \quad (6.6)$$

where $-\infty < x < \infty$ and $\psi \in [0, \pi/2]$. The solution is completely specified by two harmonic functions on the strip which are given by

$$h_1 = -i \frac{L^2}{2\sqrt{2}e^{\varphi(0)}} (\sinh w - \sinh \bar{w}) = \frac{L^2}{\sqrt{2}e^{\varphi(0)}} \cosh x \sin \psi,$$

$$h_2 = \frac{e^{\varphi(0)}L^2}{4\sqrt{2}} \left( e^w + e^\bar{w} \right) = \frac{e^{\varphi(0)}L^2}{2\sqrt{2}} e^x \cos \psi, \quad (6.7)$$

and in comparing with (6.1) we should identify $x = \bar{r}/L$.

It is interesting to compare this solution with the supergravity solutions associated with the near horizon limit of a collection of $N_3$ D3-branes ending on $N_5$ coincident D5-branes. More specifically, we want $N_3 = KN_5$ where $K \in \mathbb{Z}$, the linking number, is the same for all D5-branes. From the results of [19–23] we can write the harmonic functions for such solutions as

$$h_1 = \frac{\sqrt{\pi N_3} \ell^2_s}{\sqrt{2g_s}} \left( e^x \sin \psi + \frac{\sqrt{g_s N_3}}{2^{1/2} \sqrt{\pi K}} \log \left[ \frac{2g_s N_3^2 e^{2x} + \pi K^2 + 2^{1/2} \sqrt{\pi g_s N_3^2} K \sin \psi e^x}{2g_s N_3^2 e^{2x} + \pi K^2 - 2^{1/2} \sqrt{\pi g_s N_3^2} K \sin \psi e^x} \right] \right),$$

$$h_2 = \frac{\sqrt{\pi g_s N_3 \ell^2_s}}{\sqrt{2}} e^x \cos \psi, \quad (6.8)$$

where $g_s = e^{2\varphi(0)}$ is the string coupling constant and $\ell_s$ is the string length. In the large $x$ limit, as we approach the $\mathcal{N} = 4$ SYM end, this solution behaves as

$$h_1 = \frac{\sqrt{2\pi N_3} \ell^2_s}{\sqrt{g_s}} \left( \cosh x \sin \psi + \frac{\pi K^2}{12g_s N_3} e^{-3x} \sin 3\psi + O(e^{-5x}) \right),$$

$$h_2 = \frac{\sqrt{\pi g_s N_3 \ell^2_s}}{\sqrt{2}} e^x \cos \psi. \quad (6.9)$$

Thus, after identifying the Einstein frame AdS$_5$ curvature $\sqrt{\pi N_3} \ell^2_s = L^2$, as $x \to \infty$ we see that this solution has the same asymptotic form as (6.7), with sub-leading corrections. Moreover, note that we also obtain the expansion (6.9) by taking the limit $N_3 \to \infty$ while holding the linking number $K$ fixed.
Figure 9. A one sided Janus solution (solid lines) for the $\mathcal{N} = 1^*$ equal mass SO(3) invariant model that approaches $\text{AdS}_5$ as $\bar{r} \to -\infty$ and approaches, very rapidly, the exactly periodic $\text{AdS}_4 \times \mathbb{R}$ solution (dashed lines) as $\bar{r} \to +\infty$. The left panel plots the behaviour of the warp factor $A$ and the right panel plots the scalar fields $\alpha_1, \phi_1$ (we have not plotted $\phi_4$ for clarity).

### 6.2 Other constructions

It is straightforward to construct additional one-sided Janus solutions numerically. In fact we have found no obstruction to constructing solutions that approach the $\text{AdS}_5$ vacuum at one end and any of the $\text{AdS}_4 \times \mathbb{R}$ solutions that we have discussed in the previous sections at the other end; namely the $\mathcal{N} = 1, 2$ S-fold solutions with $\varphi$ a linear function, the more general S-fold solutions with $\varphi$ an LPP function or the periodic solution. The one-sided Janus solutions approaching the S-folds with linear dilaton do not have any turning points. The solutions approaching the S-folds with either $\varphi$ an LPP function or the periodic solution do have turning points, but the turning point data is not symmetric under the $\mathbb{Z}_2$ symmetry as we imposed for the solutions summarised in figures 3 and 6. All of these one-sided Janus solutions are regular.

To illustrate we have displayed in figure 9 a solution constructed in the $\mathcal{N} = 1^*$ equal mass SO(3) invariant model of section 4 that approaches the $\text{AdS}_5$ vacuum at $\bar{r} \to -\infty$ and the periodic $\text{AdS}_4 \times \mathbb{R}$ solution at $\bar{r} \to +\infty$. Notice that this particular Janus solution has the feature that the dilaton $\varphi$ is bounded.

### 7 Discussion

We have constructed a rich set of new S-fold solutions of type IIB string theory of the form $\text{AdS}_4 \times S^1 \times S^5$ which are dual to $\mathcal{N} = 1$ SCFTs in $d = 3$. The solutions are patched together along the $S^1$ direction using a non-trivial $\text{SL}(2, \mathbb{Z})$ transformation in the hyperbolic conjugacy class. The solutions are first constructed in $D = 5$ gauged supergravity and then uplifted to $D = 10$. In the previously known $\text{AdS}_4 \times \mathbb{R}$ solutions associated with S-folds preserving $\mathcal{N} = 1, 2, 4$ supersymmetry, the $D = 5$ dilaton is a linear function of a coordinate on the $\mathbb{R}$ direction. Crucially, in the new solutions the $D = 5$ dilaton is now a linear plus periodic (LPP) function. We also showed that some of the new families of LPP $\text{AdS}_4 \times \mathbb{R}$ solutions can be seen in a perturbative expansion about the $\mathcal{N} = 1$ S-fold solution with a linear dilaton. In addition, for the SO(3) invariant model the numerical construction of
such solutions revealed additional branches of LPP AdS4 × R solutions, not perturbatively connected with any known S-fold solutions.

An interesting feature of the new AdS4 × S1 × S5 solutions is that we can make the size of the S1 parametrically larger than the size of the S5, by carrying out the S-folding procedure after multiple periods with respect to the underlying periodic structure. This will gives rise to an interesting hierarchy of scaling dimensions in the N = 1 d = 3 SCFT.

A proposal for the \( \mathcal{N} = 4 \) SCFT in \( d = 3 \) dual to the \( \mathcal{N} = 4 \) S-folds of [3] was given in [4]. One takes the strongly coupled \( [TU(N)] \) theory of [7] and then gauges the global U(N) × U(N) global symmetry using an \( \mathcal{N} = 4 \) vector multiplet. In addition one adds a Chern-Simons term at level \( n \), where \( n \) is the integer that is used to make the S-folding identifications (see (3.23)). Proposals for the \( \mathcal{N} = 4 \) SCFT in \( d = 3 \) dual to the \( \mathcal{N} = 2 \) S-folds of [9] were also discussed in [10]. It would be very interesting to identify the \( \mathcal{N} = 1 \) SCFTs in \( d = 3 \) that are dual to the S-fold solutions of [8], the new constructions in this paper, as well as the periodic AdS4 × S1 × S5 solution of [15]. The small amount of supersymmetry makes this challenging, but one can hope that the connection with Janus solutions which we have highlighted in this paper, as well as in [15], will allow progress to be made.

We have seen that the periodic AdS4 × R solution found in [15], which uplifts to smooth AdS4 × S1 × S5 of type IIB supergravity, is a rather exceptional solution in the general constructions of this paper. It would be very interesting to know whether or not there are additional such solutions of the form AdS_d × T^n × M_k either in \( D = 10 \) or \( D = 11 \) supergravity.

We have focussed on constructing supersymmetric S-fold solutions, but one can also investigate non-supersymmetric possibilities. In fact a non-supersymmetric AdS4 × R × M5 solution of type IIB supergravity was discussed long ago in [31] and [32]. These solutions are associated with the \( D = 10 \) dilaton linear in the R direction, and have been subsequently rediscovered several times [8, 33–35]. However, in [8, 34, 35] it was argued that these solutions are unstable (in contrast to the claim in [31]) and hence are not of interest for S-folds with CFT duals.

Our constructions have also revealed a novel class of non-singular “one-sided Janus” solutions preserving \( \mathcal{N} = 1, 2 \) or 4 supersymmetry. These regular solutions approach the AdS5 vacuum on one side and an AdS4 × R solution with the \( D = 5 \) dilaton a linear function of the radial coordinate or an LPP function. We also constructed a solution that approaches the periodic AdS4 × R solution of [15] on the other side, which is both regular and has bounded dilaton. For the solution that approaches the \( \mathcal{N} = 4 \) S-fold solution with linear dilaton we were able to construct an analytic solution. Using the results of [19–23] we interpreted this solution as arising from D3-branes ending on D5-branes and it will be worthwhile to investigate this in more detail.

It seems likely that it will be possible to construct additional LPP AdS4 × R and one-sided Janus solutions within the 10 scalar truncation and more generally within the full SO(6) gauged supergravity with 42 scalars. It may also be possible to construct new type IIB solutions of the form AdS4 × S1 × SE5, where SE5 is a Sasaki-Einstein manifold, generalising the work of [14]. More generally, one can try to construct non-geometric solutions of the form AdS_d × T^n × M_k, where \( T^n \) is an \( n \)-dimensional torus and the solutions are patched together in the \( T^n \) directions using U-duality transformations [36].

A Uplifting to type IIB supergravity

A.1 The 10-scalar model in maximal gauged supergravity

We first discuss how the 10-scalar model is obtained from maximal SO(6) gauged supergravity in $D = 5$. The 42 scalars of SO(6) gauged supergravity parametrise the coset $E_{6(6)}/USp(8)$, with USp(8) the maximal compact subgroup of $E_{6(6)}$. To describe this coset space, it is convenient to work in a basis for $E_{6(6)}$ that is adapted to its maximal subgroup $SL(6) \times SL(2, \mathbb{R})$, recalling that the gauge group $SO(6) \subset SL(6)$. Following [37], we write the generators of $E_{6(6)}$ in the fundamental 27 representation in this basis as

$$X = \begin{pmatrix} -4\Lambda_I J[M \delta J N] & \sqrt{2} \Sigma_{IJK\alpha} \\ \sqrt{2} \Sigma_{MPN\alpha} & \Lambda_P K \delta^\alpha + \Lambda_\beta^\alpha \delta_P K \end{pmatrix}, \quad (A.1)$$

where the indices $I, J, \ldots = 1, 2, \ldots, 6$, raised and lowered with $\delta_{IJ}$, label the fundamental of $SL(6)$, while the indices $\alpha, \beta, \ldots = 1, 2$, raised and lowered with $\epsilon_{\alpha\beta}$, are $SL(2, \mathbb{R})$ indices. It is often convenient to consider $X$ as a 27$\times$27 matrix associated with the branching of the fundamental of $E_{6(6)}$ under $SL(6) \times SL(2, \mathbb{R})$, like $27 \rightarrow (15, 1) + (6, 2)$. From this perspective, a fundamental index of $E_{6(6)}$, $A = 1, 2, \ldots, 27$ splits according to $\{A\} = \{(IJ), I\alpha\}$, where $IJ$ are the 15 antisymmetric pairs of $SL(6)$ indices.

The non-compact part of this algebra is generated by the 20 symmetric, traceless $\Lambda_I J \in SL(6)$, the 2 symmetric, traceless $\Lambda_\alpha^\beta \in SL(2, \mathbb{R})$ and the 20 $\Sigma_{IJK\alpha}$ antisymmetric in $IJK$ and satisfying $\Sigma_{IJK\alpha} = \frac{1}{6} \epsilon_{IJKLMN} \epsilon_{\alpha\beta} \Sigma^{LMN\beta}$. It is possible to choose a gauge for the coset element such that these 42 non-compact generators are in one-to-one correspondence with the scalar fields of the gauged supergravity.

In this gauge, the truncation to the 10-scalar model discussed [16], retains the metric and the ten scalar fields $\{\beta_1, \beta_2, \bar{\alpha}_1, \bar{\alpha}_2, \bar{\alpha}_3, \bar{\phi}_1, \bar{\phi}_2, \bar{\phi}_3, \bar{\phi}_4, \bar{\phi}\}$ defined by

$$\Lambda_I J = \text{diag}(\beta_1 + \beta_2, -\bar{\alpha}_1 + \bar{\alpha}_2, \bar{\phi}_1 + \bar{\phi}_2, \bar{\phi}_3, \bar{\phi}_4),$$

$$\Lambda_\alpha^\beta = \text{diag}(\bar{\phi}, -\bar{\phi}), \quad (A.2)$$

and

$$\Sigma_{1351} = -\Sigma_{2462} = \frac{1}{2\sqrt{2}} (\phi_1 + \phi_2 + \phi_3 - \phi_4),$$

$$\Sigma_{1461} = -\Sigma_{2352} = \frac{1}{2\sqrt{2}} (-\bar{\phi}_1 + \bar{\phi}_2 + \bar{\phi}_3 + \bar{\phi}_4),$$

$$\Sigma_{2361} = -\Sigma_{1452} = \frac{1}{2\sqrt{2}} (\phi_1 - \phi_2 + \phi_3 + \phi_4),$$

$$\Sigma_{2451} = -\Sigma_{1362} = \frac{1}{2\sqrt{2}} (\bar{\phi}_1 + \bar{\phi}_2 - \bar{\phi}_3 + \bar{\phi}_4). \quad (A.3)$$
To do this we first move to a basis for each of the real scalars that the generators associated with this truncation generate four commuting copies of $\text{SO}(1,1)^2 \times \text{SU}(1,1)^4 \subset E_{6(6)}$. Specifically, if we let $B^{(1)}$, $B^{(2)}$ each generate an $\text{SO}(1,1)$, and $S_{1,2,3}^{(A)}$ for $A = 1, 2, 3, 4$ generate four commuting copies of $\text{SU}(1,1)$ satisfying

$$[S_1^{(A)}, S_2^{(A)}] = 2S_3^{(A)}, \quad [S_1^{(A)}, S_3^{(A)}] = 2S_2^{(A)}, \quad [S_2^{(A)}, S_3^{(A)}] = -2S_1^{(A)},$$

then we can explicitly identify the generators using Table 1.

These barred scalar fields are non-linearly related to the unbarred scalar fields that we use in (2.2), however they do agree at linear order. It is straightforward to demonstrate that the generators associated with this truncation generate $\text{SO}(1,1)^2 \times \text{SU}(1,1)^4 \subset E_{6(6)}$. Specifically, if we let $B^{(1)}$, $B^{(2)}$ each generate an $\text{SO}(1,1)$, and $S_{1,2,3}^{(A)}$ for $A = 1, 2, 3, 4$ generate four commuting copies of $\text{SU}(1,1)$ satisfying

The desired parametrisation of the coset is then given by

$$V = e^{\beta_1 B^{(1)} + \beta_2 B^{(2)}}, \quad \prod_a e^{s(|z^A|)}(z^A E^{(A)} + z^A F^{(A)}),$$

where

$$s(|z^A|) = \frac{1}{|z^A|} \text{arcsech} \sqrt{1 - |z^A|^2}.$$
can then be used to construct the kinetic terms for the scalar fields of the $D = 5$ 10-scalar model via
\[ \mathcal{L}^{(k)}_{10} = \frac{1}{96} \text{tr} \left( \partial_\mu \mathcal{M} \partial^\mu \mathcal{M}^{-1} \right), \] (A.9)
as given in (2.4). It will also play a distinguished role in the uplift of this model to ten dimensions as we discuss below.

The scalar potential $\mathcal{P}$ of the 10-scalar model appearing in (2.4) can be obtained from this coset representative using the general results for the form of the scalar potential in the SO(6) gauged supergravity given in [37]. To do this, and following [37], it is helpful to change to a basis adapted to USp(8) $\subset E_6(6)$ using the antisymmetric hermitian gamma matrices of Clif(7). An explicit representation is provided by the set of 8 $\times$ 8 matrices
\[ \Gamma^{0}, \Gamma^{1}, \ldots, \Gamma^{6}, \] (A.10)
where the $\sigma_1, \sigma_2, \sigma_3$ are Pauli matrices. From these one constructs
\[ \Gamma_{I,J} = \frac{1}{2} \left[ \Gamma_{I}, \Gamma_{J} \right] \quad \text{and} \quad \Gamma^{I,\alpha} = (\Gamma_{I}, i \Gamma_{I} \Gamma_{0}), \] (A.11)
whose “spinor” indices $a, b$ are USp(8) indices. In particular $(\Gamma_{I,J})^{ab}$ transforms in the 27 of USp(8), indexed by the symplectic traceless index pairs $[ab]$. The symplectic trace is taken with respect to the invariant tensor
\[ \Omega^{ab} = -\Omega_{ab} = -i (\Gamma_{0})^{ab}. \] (A.12)
Introducing the notation
\[ V^{ab} = \left( V_{IJ}^{ab}, V^{Ia0b} \right), \quad \text{and} \quad \mathcal{V} = \left( U_{IJ}^{PQ} U_{I,J,R\beta}^{K\alpha,PQ} U_{K\alpha,R\beta}^{I\beta} \right), \] (A.13)
for the coset representative in the USp(8) and SL(6) $\times$ SL(2,$\mathbb{R}$) bases, respectively, one can use (A.11) to relate the two:
\[ V_{PQ}^{ab} = \frac{1}{8} \left[ (\Gamma_{I,J})^{ab} U_{PQ,IJ}^{IJ} + 2 (\Gamma^{I,\alpha})^{ab} U_{PQ,I\alpha}^{I\alpha} \right], \]
\[ V^{K\alpha ab} = \frac{1}{4\sqrt{2}} \left[ (\Gamma_{I,J})^{ab} U^{K\alpha,IJ} + 2 (\Gamma^{I,\beta})^{ab} U^{K\alpha,I\beta} \right]. \] (A.14)
The $W$ tensors in [37] are then given by
\[ W_{abcd} = \delta_{IJ} c_{\alpha,\beta} V^{Ia0b'} V^{J3b'd'} \Omega_{a,a'} \Omega_{b,b'} \Omega_{c,c'} \Omega_{d,d'}, \quad W_{ab} = \Omega^{d,e} W_{cdab}, \] (A.15)
and the scalar potential of the SO(6) gauged supergravity is
\[ \mathcal{P} = -\frac{g^2}{32} \left( 2 W_{ab} W^{ab} - W_{abcd} W^{abcd} \right), \] (A.16)
where USp(8) indices are raised and lowered with the symplectic invariant (A.12) according to the rules implicit in (A.15). After substituting (A.6), using

\[ g = \frac{2}{L} , \]  

and some calculation we obtain (2.7) for the 10-scalar truncation.

### A.2 The uplift to type IIB supergravity

The uplift of the bosonic sector of the maximal gauged supergravity to type IIB supergravity is given in [18]. The D = 10 Einstein metric can be written in the form

\[ ds_{10}^2 = \Delta^{-2/3} \left( ds_5^2 + G_{mn} \theta^m \theta^n \right) , \]  

where \( ds_5^2 \) is the \( D = 5 \) metric, \( \theta^m, m = 1, 2, \ldots, 5 \), parametrise \( S^5 \) and the metric \( G_{mn} \) and the warp factor \( \Delta \) are defined below. The type IIB dilaton, \( \Phi \), and axion, \( C_0 \), parametrise the coset \( \text{SL}(2, \mathbb{R})/\text{SO}(2) \) and can be packaged in terms of a two-dimensional matrix via

\[ m_{\alpha\beta} = \begin{pmatrix} e^{\Phi} C_0^2 + e^{-\Phi} C_0 & -e^{\Phi} C_0 \\ -e^{-\Phi} C_0 & e^{\Phi} \end{pmatrix} , \]  

with \( \det m = 1 \). The remaining type IIB fields consist of two-form potentials \( (A_1^{(2)}, A_2^{(2)}) \), which transform as an \( \text{SL}(2, \mathbb{R}) \) doublet and from which we identify the NS-NS two-form \( B_{(2)} \) and the RR two-form \( C_{(2)} \) via

\[ B_{(2)} = A_1^{(2)} , \quad C_{(2)} = A_2^{(2)} , \]  

as well as the four-form potential \( C_{(4)} \) that is associated with the self-dual five-form flux as in [18].

We focus on uplifting the gravity-scalar sector of the \( D = 5 \) theory for which the scalar matrix \( \mathcal{M} \) introduced in (A.8) plays a key role. In the \( \text{SL}(6) \times \text{SL}(2, \mathbb{R}) \) basis we can write the components of \( \mathcal{M} \) and its inverse \( \mathcal{M}^{-1} \) as

\[ \mathcal{M} = \begin{pmatrix} M_{IJ,PQ} & M_{IJ,R^3} \\ M_{K\alpha,PQ} & M_{K\alpha,R^3} \end{pmatrix} , \quad \mathcal{M}^{-1} = \begin{pmatrix} M_{IJ,PQ} & M_{IJ,R^3} \\ M_{K\alpha,PQ} & M_{K\alpha,R^3} \end{pmatrix} . \]  

We also introduce the round metric on the five-sphere, \( \hat{G}_{mn} \), with inverse \( \hat{G}^{mn} \). We can write the Killing vectors of the round metric in terms of constrained coordinates \( Y^I \) on \( S^5 \), satisfying \( Y^I Y^I = 1 \), via

\[ K_{IJ}^m = -\frac{1}{L} \hat{G}^{mn} Y^I [\partial_n Y^J] . \]  

In term of these quantities, the ten-dimensional fields of the uplifted \( D = 5 \) gravity-scalar sector are given by

\[ G^{mn} = K_{IJ}^m K_{PQ}^n M_{IJ,PQ} , \]

\[ m_{\alpha\beta} = (m_{\alpha\beta})^{-1} = \Delta^{4/3} Y^I Y^J M^{Ia,J\beta} , \]

\[ A_{mn} = -L \epsilon^{a\beta} G_{nk} K_{IJ}^k M_{IJ,P\beta} \partial_m Y^P , \]

\[ C_{mnkl} = \frac{L^4}{4} \left( \sqrt{\hat{G}} \epsilon_{mnklp} \hat{G}^{pq} \Delta^{4/3} m_{\alpha\beta} \partial_q \left( \Delta^{-4/3} m^{\alpha\beta} \right) + \hat{\omega}_{mnkl} \right) . \]  

- 34 -
where \( d\omega = 16\text{vol}_{S^5}. \) Note that the \( D = 10 \) warp factor \( \Delta \) is defined implicitly using the fact that the axio-dilatonic matrix (A.23) satisfies \( \det m = 1. \)

Restricting now to the 10-scalar model, we can illustrate the above formulae by writing down the components of the axion and dilaton matrix:

\[
\Delta^{-4/3}m^{11} = e^{2\beta_1+2\beta_2} \left( \frac{(1+z^1)(1+z^2)(1+z^4)(1+z^4)}{(1-z^1)(1-z^2)(1-z^4)} \right) (Y_1)^2 + \left( \frac{1-z^2(1-z^1)(1-z^3)(1-z^4)}{(1-z^2)(1-z^3)(1-z^4)} \right) (Y_2)^2 \\
+ e^{2\beta_1-2\beta_2} \left( \frac{(1+z^1)(1+z^2)(1-z^3)(1-z^2)}{(1-z^2)(1-z^2)(1-z^2)} \right) (Y_3)^2 + \left( \frac{1-z^2(1-z^1)(1-z^3)(1-z^4)}{(1-z^2)(1-z^3)(1-z^4)} \right) (Y_4)^2 \\
+ e^{-4\beta_1} \left( \frac{(1+z^1)(1+z^3)(1-z^3)(1-z^3)}{(1-z^3)(1-z^3)} \right) (Y_5)^2 + \left( \frac{1-z^2(1-z^1)(1-z^3)(1-z^4)}{(1-z^2)(1-z^3)(1-z^4)} \right) (Y_6)^2
\] (A.24)

\[
\Delta^{-4/3}m^{12} = e^{2\beta_1+2\beta_2} \left( \frac{(z^2-z^3)(z^3-z^3)}{(1-z^3)(1-z^3)} \right) (Y_1)Y_2 \\
+ e^{2\beta_1-2\beta_2} \left( \frac{(z^2-z^3)(z^3-z^3)}{(1-z^3)(1-z^3)} \right) (Y_3)Y_4 \\
+ e^{-4\beta_1} \left( \frac{(z^2-z^3)(z^3-z^3)}{(1-z^3)(1-z^3)} \right) (Y_5)Y_6
\] (A.25)

\[
\Delta^{-4/3}m^{22} = e^{2\beta_1+2\beta_2} \left( \frac{(1+z^1)(1+z^2)(1+z^3)(1+z^3)}{(1-z^2)(1-z^3)} \right) (Y_1)^2 + \left( \frac{1-z^2(1-z^1)(1-z^3)(1-z^4)}{(1-z^2)(1-z^3)} \right) (Y_2)^2 \\
+ e^{2\beta_1-2\beta_2} \left( \frac{(1+z^1)(1+z^2)(1-z^3)(1-z^3)}{(1-z^2)(1-z^3)} \right) (Y_3)^2 + \left( \frac{1-z^2(1-z^1)(1-z^3)(1-z^4)}{(1-z^2)(1-z^3)} \right) (Y_4)^2 \\
+ e^{-4\beta_1} \left( \frac{(1+z^1)(1+z^3)(1-z^3)(1-z^3)}{(1-z^3)(1-z^3)} \right) (Y_5)^2 + \left( \frac{1-z^2(1-z^1)(1-z^3)(1-z^4)}{(1-z^2)(1-z^3)} \right) (Y_6)^2
\] (A.26)

There are a number of additional sub-truncations of the 10-scalar model as summarised in figure 2. In this paper we are particularly interested in the SO(3) invariant 4-scalar model as well as the SU(2) invariant 5-scalar model and their sub-truncations.

### A.2.1 The SO(3) invariant 4-scalar model

This truncation is obtained from the 10-scalar model by taking \( \beta_1 = \beta_2 = 0 \) and \( z^4 = -z^3 = -z^2. \) The truncation is invariant under \( \text{SO}(3) \subset \text{SU}(3) \subset \text{SO}(6). \) Similar to [38] a useful parametrisation of the five-sphere adapted to this isometry is given by

\[
\begin{pmatrix}
Y^1 + iY^2 \\
Y^3 + iY^4 \\
Y^5 + iY^6
\end{pmatrix} = e^{i\alpha} \cos \chi \mathcal{R} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} + ie^{i\alpha} \sin \chi \mathcal{R} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.
\] (A.27)

Here \( 0 \leq \alpha \leq 2\pi, \quad 0 \leq \chi \leq \pi/4, \quad \mathcal{R} = e^{1g_1}e^{2g_2}e^{3g_1} \) is an SO(3) rotation matrix parametrised by three Euler angles \( \omega, \xi_1, \xi_2 \) where \( g_1, g_2 \) are the \( 3 \times 3 \) matrices

\[
g_1 = e_{21} - e_{12}, \quad \text{and} \quad g_2 = e_{31} - e_{13},
\] (A.28)

with \( e_{ij} \) having a unit in the \( i, j \) position and zeroes elsewhere. In this parametrisation, the round metric on the five-sphere is written as a \( U(1) \) fibration over \( \mathbb{CP}^2 \) as

\[
d\Omega_5^2 = ds_{\mathbb{CP}^2}^2 + (d\omega - \sin 2\chi d\gamma_3)^2,
\] (A.29)
where
\[ ds_{\mathbb{C}P^2}^2 = d\chi^2 + \sin^2 \chi \tau_1^2 + \cos^2 \chi \tau_2^2 + \cos^2 \chi \tau_3^2 , \] (A.30)
and the \( \tau_{1,2,3} \) are locally left-invariant one-forms for SO(3) given by
\[
\begin{align*}
\tau_1 &= -\sin \xi_2 d\omega + \cos \xi_2 \sin \omega d\xi_1 , \\
\tau_2 &= \cos \xi_2 d\omega + \sin \xi_2 \sin \omega d\xi_1 , \\
\tau_3 &= d\xi_2 + \cos \omega d\xi_1 .
\end{align*}
\] (A.31)

This parametrisation of \( \mathbb{C}P^2 \) is cohomogeneity-one with principle orbits actually given by \( \text{SO}(3)/\mathbb{Z}_2 \subset \text{SU}(3) \) (rather than \( \text{SO}(3) \)). The singular orbits are an \( \text{RP}^2 \) at \( \chi = 0 \) and an \( S^2 \) at \( \chi = \pi/4 \) (see e.g. [39]).

After uplifting solutions in the \( \text{SO}(3) \) invariant model, the ten dimensional metric will, in general have non-trivial dependence on \( \alpha \) and more general dependence on \( \chi \) than that given in (A.31) and the symmetry will be the \( \text{SO}(3)/\mathbb{Z}_2 \) associated with the \( \tau_i \). For the further truncation to the \( \text{SU}(3) \) invariant model in figure 2, the \( \chi \) dependence will be as in (A.30), giving rise to \( \text{SU}(3) \) symmetry associated with \( \mathbb{C}P^2 \), but there will be non-trivial dependence on \( \alpha \).

A.2.2 The \( \text{SO}(3) \times \text{SO}(3) \) invariant 3-scalar model

The \( \text{SO}(3) \times \text{SO}(3) \) invariant sector has three scalars, and can be obtained from the \( \text{SO}(3) \) invariant model just discussed by setting \( z_2 = \bar{z}_2 \). Specifically, we have
\[
\begin{align*}
z^1 &= \tanh \left[ \frac{1}{2} (3\alpha_1 + \varphi - 4i\phi_1) \right] , \\
z^2 &= \tanh \left[ \frac{1}{2} (\alpha_1 - \varphi) \right] ,
\end{align*}
\] (A.32)
with \( \beta_1 = \beta_2 = 0 \). For this case we can parametrise the five-sphere using the coordinates
\[
\begin{align*}
Y_1 &= \cos \psi \sin \theta \cos \xi , \\
Y_2 &= \sin \psi \sin \tilde{\theta} \cos \tilde{\xi} , \\
Y_3 &= \cos \psi \sin \theta \sin \xi , \\
Y_4 &= \sin \psi \sin \tilde{\theta} \sin \tilde{\xi} , \\
Y_5 &= \cos \psi \cos \theta , \\
Y_6 &= \sin \psi \cos \tilde{\theta} ,
\end{align*}
\] (A.33)
with \( 0 \leq \theta, \tilde{\theta} \leq \pi, 0 \leq \xi, \tilde{\xi} \leq 2\pi \) and \( 0 \leq \psi \leq \pi/2 \). In these coordinates the round metric on the five-sphere is given by
\[
d\hat{\Omega}_5^2 = d\psi^2 + \cos^2 \psi \, d\Omega_2^2 + \sin^2 \psi \, d\tilde{\Omega}_2^2 ,
\] (A.34)
with \( d\Omega_2^2 = d\theta^2 + \sin^2 \theta \, d\xi^2 \) and \( d\tilde{\Omega}_2^2 = d\tilde{\theta}^2 + \sin^2 \tilde{\theta} \, d\tilde{\xi}^2 \). The \( \text{SO}(3) \times \text{SO}(3) \) symmetry of the gauged supergravity model is generated by the Killing vectors for each of the round two-spheres.

For this model it will be useful to write down some additional uplifting formulae. The \( D = 10 \) metric takes the form
\[
ds_{10}^2 = \Delta^{-2/3} \left[ ds_5^2 + L^2 \left( d\psi^2 + \frac{d\Omega_2^2}{e^{4\alpha_1} \sec 4\phi_1 + \tan^2 \psi} + \frac{d\tilde{\Omega}_2^2}{e^{-4\alpha_1} \sec 4\phi_1 + \cot^2 \psi} \right) \right] ,
\] (A.35)
with the $D = 10$ warp factor given below. The axion-dilaton matrix is diagonal with

\[
\begin{align*}
    m_{11} &= \Delta^{4/3} \left[ \cos^2 \psi \frac{(1 + z^1)(1 + \bar{z}^1)(1 - z^2)^2 + \sin^2 \psi (1 - z^2)^4}{(1 - |z|^2)(1 - (z^2)^2)} \right], \\
    &= \Delta^{4/3} \left[ e^{2\varphi - 2\alpha_1} \sin^2 \psi + e^{2\alpha_1 + 2\varphi} \sec 4\phi_1 \cos^2 \psi \right], \\
    m_{22} &= \Delta^{4/3} \left[ \sin^2 \psi \frac{(1 - z^1)(1 - \bar{z}^1)(1 + z^2)^2 + \cos^2 \psi (1 + z^2)^4}{(1 - |z|^2)(1 - (z^2)^2)} \right], \\
    &= \Delta^{4/3} \left[ e^{-2\varphi - 2\alpha_1} \sec 4\phi_1 \sin^2 \psi + e^{2\alpha_1 - 2\varphi} \cos^2 \psi \right],
\end{align*}
\]

and $m_{12} = m_{21} = 0$, where the $D = 10$ warp factor is given by

\[
\Delta^{4/3} = \frac{e^{2\alpha_1} \sec^2 \psi}{\sqrt{(e^{4\alpha_1} \sec 4\phi_1 + \tan^2 \psi) (e^{4\alpha_1} + \tan^2 \psi \sec 4\phi_1)}}.
\]

Thus, we have vanishing axion, $C_0 = 0$, and $e^\Phi = m_{11}$.

The NS-NS and R-R two-forms are found to be

\[
\begin{align*}
    B_{(2)} &= L^2 i \sin^3 \psi (z^2 - 1)(z^1 - \bar{z}^1) \frac{\Pi_1}{\Pi_2} \text{vol}_{\mathcal{S}^2}, \\
    C_{(2)} &= -L^2 i \cos^3 \psi (z^2 + 1)(z^1 - \bar{z}^1) \frac{\Pi_1}{\Pi_2} \text{vol}_{\mathcal{S}^2},
\end{align*}
\]

where

\[
\begin{align*}
    \Pi_1 &= z^1 \left[ (z^2 - 1) \sin^2 \psi - \bar{z}^1(z^2 + \cos 2\psi) \right] + z^2 \cos 2\psi + \bar{z}^1(z^2 - 1) \sin^2 \psi + 1, \\
    \Pi_2 &= z^1 \left[ (z^2 + 1) \cos^2 \psi + \bar{z}^1(z^2 + \cos 2\psi) \right] + z^2 \cos 2\psi + \bar{z}^1(z^2 + 1) \cos^2 \psi + 1,
\end{align*}
\]

and $\text{vol}_{\mathcal{S}^2} = \sin \theta \, d\theta \wedge d\xi$, $\text{vol}_{\mathcal{S}^2} = \sin \tilde{\theta} \, d\tilde{\theta} \wedge d\tilde{\xi}$. Finally, the four-form potential is given by

\[
C_{(4)} = \frac{L^4}{4} \hat{\omega} - \frac{L^4}{8} \sin^2 2\psi \left( \frac{z^1(z^2 + 2\bar{z}^1 - 2) + z^2(\bar{z}^1 - 4) - 2\bar{z}^1}{-3\Pi_1 - \Pi_2 + z^1(1 + z^2 - \bar{z}^1z^2) + (z^2 + 1)\bar{z}^1 - 4} \right) \frac{\text{vol}_{\mathcal{S}^2} \wedge \text{vol}_{\mathcal{S}^2}}{\Pi_1 + 3\Pi_2 - z^1z^2(z^1 + 1) + \bar{z}^1 - z^2\bar{z}^1 + \bar{z}^1 + 4},
\]

where the four-form $\hat{\omega}$ is given by

\[
\hat{\omega} = \left( 2\psi - \frac{1}{2} \sin 4\psi \right) \text{vol}_{\mathcal{S}^2} \wedge \text{vol}_{\mathcal{S}^2},
\]

and satisfies $d\hat{\omega} = 16\text{vol}_{\mathcal{S}^2}$, where the volume form is with respect to the round metric (A.34).

**A.2.3 The SU(2) invariant 5-scalar model**

This truncation is obtained from the 10-scalar model by taking $\beta_2 = 0$, $z^4 = -z^2$ and $z^3 = -z^1$. The resulting truncation is invariant under $SU(2) \subset SU(3) \subset SO(6)$. To
parametrise the five-sphere so that this symmetry is manifest, similar to [10] one can define

\begin{align}
Y^1 + iY^2 &= e^{i\frac{\xi_1 + \xi_2}{2}} \sin \rho \cos(\omega/2), \\
Y^3 + iY^4 &= e^{i\frac{-\xi_1 + \xi_2}{2}} \sin \rho \sin(\omega/2), \\
Y^5 + iY^6 &= e^{i\alpha} \cos \rho,
\end{align}

(A.42)

with \(\omega, \xi_1, \xi_2\) Euler angles of SU(2) with

\begin{align}
0 &\leq \omega \leq \pi, \quad 0 \leq \xi_1 \leq 2\pi, \quad 0 \leq \xi_2 < 4\pi,
\end{align}

(A.43)

and \(0 \leq \rho \leq \pi/2, \quad 0 \leq \alpha \leq 2\pi\). In these coordinates the metric on the round sphere takes the form

\begin{align}
\dot{\Omega}_5^2 &= d\rho^2 + \cos^2 \rho d\alpha^2 + \frac{1}{4} \sin^2 \rho \left( \tilde{\tau}_1^2 + \tilde{\tau}_2^2 + \tilde{\tau}_3^2 \right),
\end{align}

(A.44)

where the \(\tau_i\) are SU(2) left-invariant forms given in (A.31). The SU(2) symmetry then corresponds to the Killing vector fields associated with the SU(2) action. In general \(\partial_\alpha\) will not be a Killing vector of the uplifted solutions of the SU(2) invariant 5-scalar model and furthermore, the coefficients of the \(\tau_i\) will differ from that of (A.44).

We can also write \(\xi_2 = 2\alpha + \gamma\) so that

\begin{align}
Y^1 + iY^2 &= e^{i\alpha + \frac{i}{2} \xi_1 + \frac{i}{2} \gamma} \sin \rho \cos(\omega/2), \\
Y^3 + iY^4 &= e^{i\alpha - \frac{i}{2} \xi_1 + \frac{i}{2} \gamma} \sin \rho \sin(\omega/2), \\
Y^5 + iY^6 &= e^{i\alpha} \cos \rho.
\end{align}

(A.45)

We then have

\begin{align}
\dot{\Omega}_5^2 &= ds_{\mathbb{C}P^2}^2 + \left( d\alpha + \frac{1}{2} \sin^2 \rho \tilde{\tau}_3 \right)^2,
\end{align}

(A.46)

where

\begin{align}
ds_{\mathbb{C}P^2}^2 &= d\rho^2 + \frac{1}{4} \sin^2 \rho (\tilde{\tau}_1^2 + \tilde{\tau}_2^2) + \frac{1}{16} \sin^2 2\rho \tilde{\tau}_3^2,
\end{align}

(A.47)

and the \(\tilde{\tau}_{1,2,3}\) are left-invariant one-forms for SU(2)

\begin{align}
\tilde{\tau}_1 &= - \sin \gamma d\omega + \cos \gamma \sin \omega d\xi_1, \\
\tilde{\tau}_2 &= \cos \gamma d\omega + \sin \gamma \sin \omega d\xi_1, \\
\tilde{\tau}_3 &= d\gamma + \cos \omega d\xi_1.
\end{align}

(A.48)

For the uplift of the SU(2) invariant 5-scalar model, the metric will in general depend on \(\alpha\) and moreover the extra U(1) associated with rotating \(\tilde{\tau}_1\) into \(\tilde{\tau}_2\) that is manifest in (A.47) will no longer be present. Moving to the SU(3) truncation in figure 2 the uplifted metric will have a \(\mathbb{C}P^2\) factor, as in (A.47), giving rise to the SU(3) symmetry but there will be dependence on \(\alpha\), in general. Moving instead to the SU(2) \(\times\) U(1) invariant truncation in figure 2 the uplifted metric will in general have dependence on \(\alpha\), and the U(1) associated with rotating \(\tilde{\tau}_1\) into \(\tilde{\tau}_2\) that is manifest in (A.47) will be present.
A.3 The SL(2, ℝ) action in five and ten dimensions

Both the $D = 5$ maximal gauged supergravity and the type IIB supergravity are invariant under global SL(2, ℝ) transformations. Focussing on the gravity and scalar sector of the $D = 5$ theory the relationship between the two SL(2, ℝ) transformations can be made explicit using uplift formulae in (A.23).

Consider first the $D = 5$ theory in which the SL(2, ℝ) ⊂ E$_6$(6) can be generated by the $\mathbf{X}$ of (A.1) with $\Lambda^i_{\alpha \beta}$ a linear combination of the three matrices $(\Lambda^i)_{\alpha \beta}$ given by

$$
(\Lambda^1)_{\alpha \beta} = (\sigma^1)_{\alpha \beta}, \quad (\Lambda^2)_{\alpha \beta} = (\sigma^3)_{\alpha \beta}, \quad (\Lambda^3)_{\alpha \beta} = (-i\sigma^2)_{\alpha \beta},
$$

(A.49)

Explicitly, in terms of the 27 dimensional representation the SL(2, ℝ) generators are thus

$$
\mathbf{X} \big|_{\text{SL}(2, \mathbb{R})} = \begin{pmatrix}
0_{15 \times 15} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} \\
(\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} \\
(\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} \\
(\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} \\
(\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta} & (\Lambda^i)_{\alpha \beta}
\end{pmatrix}.
$$

(A.50)

A finite SL(2, ℝ) transformation in the $D = 5$ theory, using the $i$th generator, can then be written $S^i_{(5)} = e^{\mathbf{X} \big|_{\text{SL}(2, \mathbb{R})}}$ where $c$ is constant. This transformation acts on the scalar matrix $\mathcal{M}$ given in (A.8) via

$$
\mathcal{M} \rightarrow \mathcal{M}' = S^i_{(5)} \cdot \mathcal{M} \cdot S^i_{(5)}^T.
$$

(A.51)

From this one can infer the corresponding transformation of the scalars parametrising the coset which, in general, is non-linear. For the specific case of the transformation associated with the $i = 3$ generator, one finds the following action on the ten-scalar model:

$$
\begin{align*}
\beta_1 &\rightarrow \beta_1, \\
\beta_2 &\rightarrow \beta_2, \\
z^1 &\rightarrow \frac{z^1 + \tanh \frac{c}{2}}{1 + \tanh \frac{c}{2} z^2}, \\
z^2 &\rightarrow \frac{z^2 - \tanh \frac{c}{2}}{1 - \tanh \frac{c}{2} z^2}, \\
z^3 &\rightarrow \frac{z^3 - \tanh \frac{c}{2}}{1 - \tanh \frac{c}{2} z^4}, \\
z^4 &\rightarrow \frac{z^4 + \tanh \frac{c}{2}}{1 + \tanh \frac{c}{2} z^4}.
\end{align*}
$$

(A.52)

From (2.2) one can conclude that this transformation is equivalent to a simple shift in the five dimensional field $\varphi \rightarrow \varphi + c$. Also note that the SL(2, ℝ) transformations associated with the $i = 1, 3$ generators take us outside the 10-scalar truncation and will not play a role in this paper.

We now turn to the SL(2, ℝ) action in $D = 10$. From (A.23) we can conclude that the $D = 5$ transformation by the element $S^i_{(5)}$ is equivalent to a transformation by

$$
S^i_{(10)} = e^{(\Lambda^i)_{\alpha \beta}},
$$

(A.53)
in the $D = 10$ theory. For example, and of most interest, the transformation associated with the $i = 2$ generator gives rise to

$$m^{-1} \rightarrow m'^{-1} = S^2_{(10)} \cdot m^{-1} \cdot S^2_{(10)}^T.$$  
(A.54)

This transformation is equivalent to

$$m_{\alpha\beta} \rightarrow m'_{\alpha\beta} = \left( e^{-2c} m_{11} \quad m_{12} \quad m_{12} \quad e^{2c} m_{22} \right),$$  
(A.55)

and translates, in turn, into the following simple transformation of the $D = 10$ dilaton and axion:

$$\Phi \rightarrow \Phi + 2c \quad \text{and} \quad C_0 \rightarrow e^{-2c} C_0.$$  
(A.56)

The transformation by $S^2_{(10)}$ plays a key role for our solutions, as it allows one to S-fold the $D = 5$ solutions, as we discuss in the text (note that we call this transformation simply $S$ in (3.18)).

In checking that the S-fold procedure we employ does not break supersymmetry it is also useful to see how an $S^2_{(5)} \in \text{SL}(2, \mathbb{R})$ transformation acts on the $D = 5$ supersymmetry parameters. A transformation by any element of the $E_6(6)$ global symmetry group is associated with a local compensating $\text{USp}(8)$ transformation, $\mathcal{H}$, which acts on the fermions. For the action of $S^2_{(5)}$ we find that $H \in U(1)^4 \subset \text{USp}(8)$, in the fundamental representation, is explicitly given by

$$\mathcal{H} = \left( \begin{array}{cccccccc}
\frac{k_1 + k_3}{2} & 0 & 0 & 0 & \frac{k_1 - k_3}{2} & 0 & 0 & 0 \\
0 & \frac{k_2 + k_2}{2} & 0 & 0 & \frac{k_2 - k_2}{2} & 0 & 0 & 0 \\
0 & 0 & \frac{k_1 + k_3}{2} & 0 & 0 & \frac{k_1 - k_3}{2} & 0 & 0 \\
0 & 0 & 0 & \frac{k_1 + k_3}{2} & 0 & 0 & \frac{k_1 - k_3}{2} & 0 \\
0 & \frac{k_2 - k_2}{2} & 0 & 0 & \frac{k_2 + k_2}{2} & 0 & 0 & 0 \\
0 & 0 & \frac{k_3 - k_3}{2} & 0 & 0 & \frac{k_3 + k_3}{2} & 0 & 0 \\
0 & 0 & 0 & \frac{k_4 - k_4}{2} & 0 & 0 & \frac{k_4 + k_4}{2} & 0 \\
0 & 0 & 0 & 0 & \frac{k_4 - k_4}{2} & 0 & 0 & \frac{k_4 + k_4}{2} \\
\end{array} \right),$$  
(A.57)

with

$$k_1 = \left( \frac{g_1 g_2 g_3 g_4}{g_1 g_2 g_3 g_4} \right)^{1/4}, \quad k_2 = \left( \frac{g_1 g_2 g_3 g_4}{g_1 g_2 g_3 g_4} \right)^{1/4},$$  

$$k_3 = \left( \frac{g_1 g_2 g_3 g_4}{g_1 g_2 g_3 g_4} \right)^{1/4}, \quad k_4 = \left( \frac{g_1 g_2 g_3 g_4}{g_1 g_2 g_3 g_4} \right)^{1/4},$$  
(A.58)

and

$$g_1 = 1 + \tanh \left( c/2 \right) z^1, \quad g_2 = 1 - \tanh \left( c/2 \right) z^2,$$

$$g_3 = 1 - \tanh \left( c/2 \right) z^3, \quad g_4 = 1 + \tanh \left( c/2 \right) z^4.$$  
(A.59)

The action on the supersymmetry parameters $\varepsilon$ can be seen by diagonalising the $W$-tensor $W_{ab}$ of $D = 5$ gauged supergravity (A.15) and restricting $\varepsilon^a$ to lie within the space spanned

\[ - 40 - \]
by the eigenvectors of $W_{ab}$ with eigenvalues $e^{K/2}W$ (1st) and $e^{K/2}W$ (5th). In this basis the USp(8) transformation is found to be

$$\hat{\mathcal{H}} = \text{diag} \left( k_1, k_2, k_3, k_4, \bar{k}_1, \bar{k}_2, \bar{k}_3, \bar{k}_4 \right).$$  \hspace{1cm} (A.60)

The dilaton shift action can also be seen as a Kähler transformation acting in the $D = 5$ theory, as noted in [15]. Under $\varphi \rightarrow \varphi + c$ we have $K \rightarrow K + f + \bar{f}$ and $W \rightarrow e^{-f}W$ with $f = f(z^A)$ given by

$$e^f = \cosh^4(c/2) g_{12} g_{34}. \hspace{1cm} (A.61)$$

Under this transformation the preserved supersymmetries of the BPS equations transform as

$$\epsilon_1 \rightarrow e^{(f - \bar{f})/4} \epsilon_1 \quad \text{and} \quad \epsilon_2 \rightarrow e^{-(f - \bar{f})/4} \epsilon_2 \quad \text{i.e.} \quad \epsilon_1 \rightarrow k_1 \epsilon_1 \quad \text{and} \quad \epsilon_2 \rightarrow \bar{k}_1 \epsilon_2.$$  

This shows that the dilaton shift is realised by an SL(2, $\mathbb{R}$) transformation that is also acting as an SL(2, $\mathbb{R}$) transformation on the preserved supersymmetries. This allows us to conclude that the S-folding procedure will preserve the supersymmetry of the $D = 5$ solutions as noted in the text.

A.4 The $\mathcal{N} = 4$ one-sided Janus solution in type IIB

Here we show that the one-sided Janus solution (6.1), after being uplifted to $D = 10$, can be cast into the form of the general AdS$_4$ solutions of type IIB which preserve $\mathcal{N} = 4$ supersymmetry [19, 20].

In [19, 20] they consider the type IIB Einstein metric written in the form

$$ds^2 = f_2^2 ds^2_{\text{AdS}_4} + f_1^2 d\Omega_2^2 + f_2^2 d\tilde{\Omega}_2^2 + ds^2(\Sigma), \hspace{1cm} (A.62)$$

where $ds^2(\Sigma)$ is the metric on a Riemann surface. Introducing a complex coordinate $w$ on $\Sigma$ we write

$$ds^2(\Sigma) = 4\rho^2 dw d\bar{w}, \hspace{1cm} (A.63)$$

where $\rho$ as well as $f_1, f_2, f_4$ are functions of $w, \bar{w}$. To specify a solution in the language of [19], it is sufficient to provide two harmonic functions on the Riemann surface, $h_1, h_2$. To do so, as in [40], one can introduce the real functions

$$W \equiv \partial_w h_1 \partial_{\bar{w}} h_2 + \partial_w h_2 \partial_{\bar{w}} h_1, \quad N_1 \equiv 2h_1 h_2 |\partial_w h_1|^2 - h_1^2 W, \quad N_2 \equiv 2h_1 h_2 |\partial_w h_2|^2 - h_2^2 W. \hspace{1cm} (A.64)$$

Then, for example, the $D = 10$ dilaton $\Phi$ is given by

$$e^{2\Phi} = \frac{N_2}{N_1}, \hspace{1cm} (A.65)$$

while the metric functions have the form

$$\rho^8 = \frac{W^2}{h_1^4 h_2^4} N_1 N_2, \quad f_1^2 = 2e^{\frac{\Phi}{2}} h_1^2 \sqrt{\frac{W}{N_1}}, \quad f_2^2 = 2e^{-\frac{\Phi}{2}} h_2^2 \sqrt{\frac{W}{N_2}}, \quad f_4^2 = 2e^{-\frac{\Phi}{2}} \sqrt{\frac{W}{N_2}}. \hspace{1cm} (A.66)$$
To connect with the uplifted one sided Janus solution (6.1) we take the Riemann surface to be an infinite strip and write
\[ w = \frac{\tilde{r}}{L} + i\psi, \] (A.67)
with \(-\infty < \tilde{r} < \infty\) and \(\psi \in [0, \pi/2]\). We then take the harmonic functions to be
\[ h_1 = -ie^{-\varphi(\cdot)} \frac{L^2}{2\sqrt{2}} (\sinh w - \sinh \tilde{w}) = \frac{e^{-\varphi(\cdot)} L^2}{\sqrt{2}} \frac{\tilde{r}}{L} \sin \psi, \]
\[ h_2 = \frac{e^{\varphi(\cdot)} L^2}{4\sqrt{2}} \left( e^w + e^{\tilde{w}} \right) = \frac{e^{\varphi(\cdot)} L^2}{2\sqrt{2}} \frac{e^{\tilde{r}/L}}{\sin \psi}, \] (A.68)
and hence
\[ W = -\frac{L^4}{16} \sin 2\psi, \]
\[ N_1 = \frac{e^{-2\varphi(\cdot)} L^8}{256} \sin 2\psi \left( 1 + e^{-2\tilde{r}/L} \right) \left( 2 + 2e^{2\varphi/L} \cos^2 \psi + e^{4\varphi/L} - \cos 2\psi \right), \]
\[ N_2 = \frac{e^{2\varphi(\cdot)} L^8}{256} e^{2\varphi/L} \sin 2\psi \left( 2 + e^{2\varphi/L} + \cos 2\psi \right). \] (A.69)

With a little effort we can show that this agrees with the uplift of (6.1) after using the results\(^{14}\) in section A.2.2. For example, in both cases the \(D = 10\) dilaton is given by
\[ e^{2\Phi} = \frac{e^{4\varphi(\cdot)} e^{4\varphi/L} \left( 2 + e^{2\varphi/L} + \cos 2\psi \right)}{(1 + e^{2\varphi/L}) \left( 2 + 2e^{2\varphi/L} \cos^2 \psi + e^{4\varphi/L} - \cos 2\psi \right)}. \] (A.70)

Notice that as \(\tilde{r} \to \infty\), where the solution approaches the \(\text{AdS}_5\) vacuum, we have \(e^{2\Phi} \to e^{4\varphi(\cdot)}\) while as \(\tilde{r} \to -\infty\) we have \(e^{2\Phi} \to 0\).

B Holographic renormalisation

The holographic renormalisation for the 10-scalar truncation was discussed in detail in [15] (see also the closely related discussion in [16]). The counter term action required to remove all divergences was given in (B.7) of [15]. In addition a set of finite counter terms was given in (B.8) of [15], invariant under the discrete symmetries (2.8)–(2.10), which depends on 14 constant “\(\delta\)-coefficients” (in particular it was assumed that they are independent of sources for \(\varphi\)). By analysing the conditions for configurations preserving ISO(2,1) symmetry to have a local energy density that is a total spatial derivative, it was shown, in the notation of [15] that
\[ \delta_{4(1)} = -\frac{1}{4} + 2\delta_\beta, \quad \delta_{4(3)} = \frac{3}{4} + 2\delta_\beta, \quad \delta_{\partial\varphi(1)} = 2\delta_\alpha. \] (B.1)

\(^{14}\)In fact to get an exact match with the metric and also for the two-form and four-form potentials in (A.33) we should relabel \(\tilde{\theta} \to \pi - \theta\), \(\tilde{\xi} \to \xi + \pi\) as well as \(\theta \to \tilde{\theta}\), \(\xi \to \tilde{\xi}\), so that \(d\Omega_2 \leftrightarrow d\tilde{\Omega}_2\) and \(\text{vol}_{S^2} \leftrightarrow -\text{vol}_{S^2}\) and \(\text{vol}_{S^2} \to \text{vol}_{S^2}\).
The finite counter terms combined with this condition are consistent with a renormalisation scheme preserving $\mathcal{N} = 1$ supersymmetry of the $d = 4$ boundary theory.

It is of interest to determine a scheme that is consistent with the full $\mathcal{N} = 4$ supersymmetry of the boundary theory. While the full analysis is left for future work, here we make a simple observation that further constrains the $\delta$-coefficients. The finite counterterms considered above are invariant under the discrete symmetries (2.8)–(2.10) which preserve the superpotential and hence preserve the supercharge associated with the $\mathcal{N} = 1$ supersymmetry that is being considered in the BPS equations. One can check that the action is also invariant under the additional discrete symmetries

$$
\begin{align*}
 z^1 &\leftrightarrow z^4, \quad z^2 \leftrightarrow z^3; \quad \Leftrightarrow \phi_1 \leftrightarrow \phi_4, \quad \phi_2 \leftrightarrow \phi_3, \quad (\alpha_2, \alpha_3) \rightarrow - (\alpha_2, \alpha_3), \\
 z^1 &\leftrightarrow -z^2, \quad z^3 \leftrightarrow -z^4; \quad \Leftrightarrow \phi_2 \leftrightarrow \phi_4, \quad \phi_1 \leftrightarrow \phi_3, \quad (\alpha_1, \alpha_3) \rightarrow - (\alpha_1, \alpha_3), \\
 z^1 &\leftrightarrow -z^3, \quad z^2 \leftrightarrow -z^4; \quad \Leftrightarrow \phi_3 \leftrightarrow \phi_4, \quad \phi_1 \leftrightarrow \phi_2, \quad (\alpha_1, \alpha_2) \rightarrow - (\alpha_1, \alpha_2). 
\end{align*}
\tag{B.2}
$$

These symmetries do not preserve the BPS equations but instead transform the supercharges into each other; they are the generalisation of (3.3) of [41] to include the $\alpha_i$ scalars. For a scheme preserving $\mathcal{N} = 4$ supersymmetry we should therefore impose that the finite counterterms are also invariant under these discrete symmetries and hence we should also impose in (B.8) of [15]:

$$
\delta_{\phi(2)} = \delta_{\phi(1)}, \quad \delta_{\phi(4)} = \delta_{\phi(3)}, \quad \delta_{\phi^2(2)} = \delta_{\phi^2(1)}, \quad \delta_{R\phi^2(2)} = \delta_{R\phi^2(1)}.
\tag{B.3}
$$

To illustrate the impact of these conditions, we now consider the equal mass, $\mathcal{N} = 1^*$ SO(3) invariant truncation which depends on four scalars $\phi_1 = \phi_2 = \phi_3, \phi_4, \alpha_1 = \alpha_2 = \alpha_3$ and $\varphi$, with $\beta_1 = \beta_2 = 0$. With a $D = 5$ metric of the form

$$
ds^2 = e^{2A(\bar{r}, x)}(dt^2 - dy_1^2 - dy_2^2) - e^{2V(\bar{r}, x)} dx^2 - d\bar{r}^2,
\tag{B.4}
$$

with all scalar fields functions of $(\bar{r}, x)$ only, we can use the schematic expansion as we approach the boundary at $\bar{r} \to \infty$:

$$
\begin{align*}
A &= \frac{\bar{r}}{L} + \Omega + \cdots + A(v)e^{-\bar{r}/L} + \cdots, \\
V &= \frac{\bar{r}}{L} + \Omega + f + \cdots + V(v)e^{-\bar{r}/L} + \cdots, \\
\phi_2 &= \phi_3 = \phi_1 = \phi_1(s)e^{-\bar{r}/L} + \cdots + \phi_1(v)e^{-3\bar{r}/L} + \cdots, \\
\phi_4 &= \phi_4(s)e^{-\bar{r}/L} + \cdots + \phi_4(v)e^{-3\bar{r}/L} + \cdots, \\
\alpha_2 &= \alpha_3 = \alpha_1 = \alpha_1(s)\frac{\bar{r}}{L}e^{-2\bar{r}/L} + \alpha_1(v)e^{-2\bar{r}/L} + \cdots, \\
\varphi &= \varphi(s) + \cdots + \varphi(v)e^{-4\bar{r}/L} + \cdots,
\end{align*}
\tag{B.5}
$$

where $\phi_1(s), \phi_4(s), \alpha_1(s), \varphi(s)$ determine the source terms for the scalar operators in (2.3)
and, as in [15], we focus on $\varphi(s) = 0$. Now using (B.1) and (B.3) in (B.37) of [15] we obtain

\[ \langle O_{\alpha_1} \rangle = \langle O_{\alpha_2} \rangle = \langle O_{\alpha_3} \rangle = \frac{1}{4\pi GL} \left( \alpha_{1,(v)} - 2\delta_\alpha \alpha_{1,(s)} \right), \]

\[ \langle O_{\phi_1} \rangle = \langle O_{\phi_2} \rangle = \langle O_{\phi_3} \rangle = \frac{1}{2\pi GL} \left( \phi_{1,(v)} + \frac{5}{6} \phi_{1,(s)}^3 - \frac{9 - 2\delta_{4(5)}}{3} \phi_{1,(s)}^2 \phi_{4,(s)} \right. \]

\[ - \left. \frac{1 + 16\delta_\beta}{6} \phi_{1,(s)} \phi_{4,(s)}^2 + \frac{L^2}{4} \left( 1 + 4\delta_\alpha \right) \Box \phi_{1,(s)} - \frac{L^2}{24} \left( 1 + 2\delta_{R\phi^2(1)} \right) R \phi_{1,(s)} \right), \]

\[ \langle O_{\phi_4} \rangle = \frac{1}{2\pi GL} \left( \phi_{4,(v)} - \frac{9 - 2\delta_{4(5)}}{3} \phi_{1,(s)}^3 - \frac{1 + 16\delta_\beta}{2} \phi_{1,(s)}^2 \phi_{4,(s)} + \frac{7 + 32\delta_\beta}{6} \phi_{4,(s)}^3 \right. \]

\[ + \left. \frac{L^2}{4} \left( 1 + 4\delta_\alpha \right) \Box \phi_{4,(s)} - \frac{L^2}{24} \left( 1 + 2\delta_{R\phi^2(1)} \right) R \phi_{4,(s)} \right), \]

\[ \langle O_\varphi \rangle = \frac{1}{\pi GL} \left( \varphi_{(v)} - \frac{3}{4} (\alpha_{1,(s)} - 4\alpha_{1,(s)}) (\phi_{1,(s)}^2 - \phi_{1,(s)} \phi_{4,(s)}) \right). \quad \text{(B.6)} \]

We now consider the further truncation to the \( SO(3) \times SO(3) \) invariant truncation which depends on three scalars $\phi_1 = \phi_2 = \phi_3 = -\phi_4$, $\alpha_1 = \alpha_2 = \alpha_3$ and $\varphi$. Correspondingly we should set $\phi_{4,(s)} = -\phi_{1,(s)}$, $\phi_{4,(v)} = -\phi_{1,(v)}$ and then (B.6) becomes

\[ \langle O_{\alpha_1} \rangle = \langle O_{\alpha_2} \rangle = \langle O_{\alpha_3} \rangle = \frac{1}{4\pi GL} \left( \alpha_{1,(v)} - 2\delta_\alpha \alpha_{1,(s)} \right), \]

\[ \langle O_{\phi_1} \rangle = \langle O_{\phi_2} \rangle = \langle O_{\phi_3} \rangle = -\langle O_{\phi_4} \rangle = \frac{1}{2\pi GL} \left( \phi_{1,(v)} + \left( \frac{11 - 2\delta_{4(5)}}{3} - \frac{8\delta_\beta}{3} \phi_{1,(s)}^3 \right) \right. \]

\[ + \left. \frac{L^2}{4} \left( 1 + 4\delta_\alpha \right) \Box \phi_{1,(s)} - \frac{L^2}{24} \left( 1 + 2\delta_{R\phi^2(1)} \right) R \phi_{1,(s)} \right), \]

\[ \langle O_\varphi \rangle = \frac{1}{\pi GL} \left( \varphi_{(v)} - \frac{3}{2} (\alpha_{1,(s)} - 4\alpha_{1,(s)}) \phi_{1,(s)}^2 \right). \quad \text{(B.7)} \]

We emphasise that if we had not imposed (B.3), then we would not have obtained the equality $\langle O_{\phi_1} \rangle = \langle O_{\phi_2} \rangle = \langle O_{\phi_3} \rangle = -\langle O_{\phi_4} \rangle$.

This refinement of the RG scheme does not play a direct role for the one point functions in section 6.1 since the source terms for the scalars all vanish (after a possible shift of the dilaton). However, it does impact upon other observables. We also note here that to get the expectation values as given in (6.3), one should follow the discussion in section C.3 of [15].

\footnote{Note that we have corrected a typo in (B.37) of [15]: the sign of the third term on the right hand side of $\langle O_{\phi_4} \rangle$ should be $+$ and not $-$.}
