## ABSTRACT

Supply Chain Formation (SCF) is the process of determining the participants in a supply chain, who will exchange what with whom, and the terms of the exchanges. Mixed multi-unit combinatorial auctions (MMUCAs) offer a high potential to solve SCF problems, and thus be employed for the automated assembly of supply chains of agents. In this paper we present MMUCATS, a test suite for MMUCAs that allows researchers to test, compare, and improve their winner determination algorithms for MMUCAs.

## Categories and Subject Descriptors

F.2 [Analysis of Algorithms and Problem Complexity]: Nonnumerical Algorithms and Problems

## General Terms

Algorithms, Experimentation, Economics

## Keywords

Combinatorial Auctions, Supply Chain Management

## 1. SUPPLY CHAIN FORMATION PROBLEM

According to [6], “Supply Chain Formation (SCF) is the process of determining the participants in a supply chain, who will exchange what with whom, and the terms of the exchanges”. Combinatorial Auctions (CAs) are a negotiation mechanism well suited to deal with complementarities among the goods at trade. Since production technologies often have to deal with strong complementarities, SCF automation appears as a very promising application area for CAs. However, whilst in CAs the complementarities can be simply represented as relationships among goods, in SCF the complementarities involve not only goods, but also production relationships along several levels of the supply chain.

In [2] Cerquides et al. introduce the so-called mixed multi-unit combinatorial auctions (MMUCAs), a generalisation of

the standard model of CAs. Rather than negotiating over goods, in MMUCAs the auctioneer and the bidders can negotiate over *transformations*, each one characterized by a set of input goods and a set of output goods. A bidder offering a transformation is willing to produce its output goods after having received its input goods along with the payment specified in the bid. While in standard combinatorial auctions, a solution to the winner determination problem (WDP) is a set of atomic bids to accept, in MMUCAs, the *order* in which the auctioneer “uses” the accepted transformations matters. Thus, a *solution* to the WDP is a *sequence of transformations*. For instance, if bidder *Joe* offers to make dough if provided with butter and eggs, and bidder *Lou* offers to bake a cake if provided with enough dough, the auctioneer can accept both bids whenever he uses Joe’s transformation before Lou’s to obtain cakes.

MMUCAs do offer a high potential to be employed for the automated assembly of supply chains of agents. However, in order for MMUCAs to be effectively applied to SCF, we must ensure computational tractability while preserving optimality. Unfortunately this is not a straightforward task because, as discussed in [3, 5], the tractability of the WDP is largely affected by the topological structure of the problem (e.g. cycles in the supply chain). In order to address this and other problems, we propose to endow researchers with a test suite where they can investigate computationally efficient solvers for the MMUCA WDP, along the lines of the successful CATS suite [4] for combinatorial auctions.

## 2. MMUCATS A TEST SUITE FOR MMUCA

MMUCATS has been conceived as a Java-based, graphical test suite for MMUCAs to help researchers test, compare, and improve their winner determination algorithms. In what follows we highlight its most salient features:

**Artificial data set generation.** MMUCATS encloses an algorithm to generate artificial data sets (as described in [5]) that are representative of the sort of scenarios a WD algorithm is likely to encounter. The algorithm takes inspiration from the structure of supply chains. Thus, it allows: (i) to generate supply chain structures with varying number of *tiers* (levels); (ii) to flexibly distribute transformations between tiers so that transformations vary from very simple to highly *complex* (in terms of goods involved per transformation) between tiers; (iii) to flexibly distribute transformations between tiers so that tiers are connected by different production structures (e.g. cycles or a transformation whose input goods are beyond the preceding tier and whose output goods go beyond the next tier); and (iv) to flexi-
