Abstract

Currently available drugs for treatment of Leishmania infections are highly toxic and drug resistance to first-line therapies has been observed. New, safer and more effective drugs are urgently needed to improve clinical resolution of the disease and reduce the risks associated with it. High-throughput screening of new compounds against cultured promastigotes is easy to perform, but the results are poorly predictive of in vivo efficacy. Intra-macrophage amastigote models provide a better proxy of the clinically relevant stage of disease and should be routinely implemented in the search for new anti-leishmanial agents, despite being labor-intensive.

This study describes the use of a duplex quantitative Reverse-Transcriptase PCR (qRT-PCR) for assessment of drug activity against Leishmania intracellular amastigotes and their host cells. The assay simultaneously quantifies Leishmania 18S ribosomal RNA and the human β2-microglobulin (β-2M) mRNA, used for monitoring drug cytotoxicity and test performance. Accurate determination of parasite viability by the newly developed qRT-PCR was confirmed by parallel assessment of compound performance against standard microscopy. Highly reproducible anti-leishmanial activities were obtained with a set of structurally- and pharmacologically-diverse compounds, whose toxicity against host cells correlated with a low β-2M amplification. Sensitive and versatile, this duplex qRT-PCR offers a valuable tool for assessment of drug activities against Leishmania amastigotes and their host cells.

**Introduction**

Leishmaniasis is caused by protozoan parasites of the genus *Leishmania*. In humans, the parasite causes a wide spectrum of clinical syndromes, from self-healing skin ulcers to severe, life-threatening disease, following visceralization in the lymphoid organs. Approximately 12 million people are currently infected with the disease and an estimated 2 million new cases occur each year, of which 1.5 million of cutaneous leishmaniasis and 0.2-0.4 million of visceral leishmaniasis.\(^1\) Chemotherapy remains the only effective way to treat all forms of disease, but current drugs are toxic, expensive and increasingly inefficacious due to parasite resistance, compelling the search for new anti-leishmanial agents.\(^2-4\)

Development of new drugs relies on the screening of large numbers of compounds, for which robust and highly performing assays are required. Axenic, insect stage promastigotes provide a simple model for evaluation of anti-leishmanial drug activity at high-throughput, but the resulting data have little value in animals, due to the metabolic and ecological differences that distinguish promastigotes from the mammalian amastigote stage.\(^5,6\) Macrophages carrying *Leishmania* amastigotes resemble the clinically relevant phase of disease, and have therefore been recognized as most predictive of clinical efficacy.\(^6,7\) Traditionally, drug activity against this stage is measured by microscopy counting of the percentage of infected macrophages and the number of amastigotes therein, a method which is labor-intensive and time-consuming.\(^8\)

In addition, establishment of parasite viability through staining procedures is difficult and often subjective, leading to potential inaccuracies in potency estimation.\(^6\) Recent introduction of reporter gene assays for engineered *Leishmania* spp.\(^9-12\) has overcome this problem, but the use of parasite-recombinant markers that is associated with these techniques require stringent culturing conditions and prevent from assessing macrophage viability. Automated image-based assays provide a valuable alternative in this respect, enabling high-content examinations of compound activity against both *Leishmania* amastigotes and their host cells.\(^13\)

Their implementation across non-dedicated facilities, however, remains limited, due to the sophisticated equipment required. PCR technology is nowadays widely available and has proven useful in monitoring anti-leishmanial drug efficacy at both *in vitro* and *in vivo* level.\(^14,15\) Several real-time quantitative PCR (qPCR) assays have been developed for detection of viable *Leishmania* parasites and assessment of drug performance,\(^16-18\) either through SYBR Green or fluorogenic probe technology. Importantly, these tests lacked an internal control that surveyed for test performance and monitored drug toxicity against the mammalian host cells.

The present study validates the use for drug screening purposes of a duplex Reverse-Transcriptase qPCR (qRT-PCR) simultaneously assessing for toxicity against *Leishmania* intracellular amastigotes and their host cells. Amplification of *Leishmania*-specific 18S ribosomal RNA was combined with the human β2-microglobulin (β2-M) mRNA, producing a sensitive and highly accessible tool to accurately measure anti-proliferative effects against the relevant stage of leishmaniasis.
Materials and Methods

Compounds
Amphotericin B (Calbiochem, Nottingham, UK), miltefosine, paromomycin, H-89 dihydrochloride hydrate and imipramine hydrochloride (all from Sigma-Aldrich Co., St. Louis, USA) were used for pharmacological validation of the qRT-PCR, alongside with the newly synthesized compounds (VUF11852, VUF11854, VUF11856, VUF11857 and VUF13577) kindly provided by Dr. K. Orrling (VU University, Amsterdam, the Netherlands) within the framework of a collaborative project (T4-302, Ti Pharma) for developing new phosphodiesterase inhibitors as potential anti-leishmanial drugs. Drug stock solutions (10 mM) were constituted in water, ethanol or DMSO, according to the compound solubility. Further dilutions of the drugs were performed in culture medium, possibly supplemented with the corresponding solvent to yield equal medium composition over the dilution series. For infected macrophages used as untreated controls (without drugs), DMSO, ethanol or water were added to the culture medium at the same concentrations as for the drugs.

Leishmania promastigotes
Leishmania donovani 1S promastigotes (MHOM/SD/68/1S) were maintained axenically at 27°C, by serial passage in RPMI 1640 medium (Gibco, Bleiswijk, the Netherlands) supplemented with 25 mM HEPES, 2 mM L-glutamine and 10% fetal calf serum (FCS, Sigma-Aldrich Co.).

Leishmania intracellular amastigote model
THP-1 cells (human acute monocyte leukemia cell line) were cultured in RPMI 1640 medium supplemented with 25 mM HEPES, 2 mM L-glutamine, 10% FCS, penicillin (50 IU/mL) and streptomycin (50 µg/mL), to a density of 500,000 cells per mL. Cells (100 µL) were transferred to a 96-well culture plate for later testing by PCR and to a Lab Tek 16-well chamber-slide (Nunc, Waltham, USA) for microscopy counting. Next, 100 µL of cell culture medium containing 20 ng/mL of phorbol myristate acetate (PMA, Sigma-Aldrich Co.) were added to each well in order to differentiate the THP-1 cells into adherent macrophage-like cells. After 2 days of incubation at 37°C, 5% CO₂, cells were washed 3 times with culture medium to remove non-adherent cells. Infection of macrophages was performed with 200 µL of L. donovani 1S promastigotes at a density of 2.5 million parasites/mL. After 18-h of incubation at 37°C, 5% CO₂, cells were washed to remove excess of promastigotes and further incubated for 3 days with culture medium containing the appropriate concentration of test compound. Untreated (containing no drugs) and uninfected (containing no parasites and no drugs) controls were included in all drug experiments using the same culture medium. Two independent experiments testing a total of 10 different compounds were performed in triplicate for PCR and in duplicate for microscopy.

Analysis of intracellular amastigote content by microscopy
After 72-h of incubation at 37°C, 5% CO₂, the slides were removed from the culture chambers, methanol-fixed and Field’s-stained. Their examination was performed with a light microscope (Leica, Rijswijk, the Netherlands), using a 100X objective. Results were expressed by mean of the parasite index (percentage of infected macrophages × mean number of amastigotes per macrophage), after examining a minimum of 100 macrophages per sample. Infection was judged to be adequate if more than
70% of the macrophages in the untreated control were infected.

**Analysis of intracellular amastigote content by qRT-PCR**

After removal of culture medium, 0.75 mL of Trizol® (Invitrogen, Bleiswijk, the Netherlands) was added to all wells for cell lysis and the lysates were transferred to 1.5 mL tubes. RNA was Trizol®-extracted and purified according to manufacturer’s instructions. Residual DNA was further removed from all extracts by DNase digestion with Turbo DNase (Ambion, Invitrogen), performed according to the manufacturer’s instructions. A duplex qRT-PCR was performed for quantification of both *Leishmania* and human RNAs. The *Leishmania* qRT-PCR consisted of the forward primer 5’-CCAAAGTGTGGAGATCGAAG-3’, the reverse primer 5’-GGCCGGTAAAGGCCGAATAG-3’ and the probe 5’-6FAM-ACCATTGTAGTCCACACTGC-3’-NFQ conjugated to a minor groove binder (MGB) to increase the binding affinity of the probe to the target.\(^{20}\) For β-2M, the sense primer 5’-GGCTATCCAGCGTACTCCAA-3’ and the anti-sense primer 5’-GATGAAACCAGACACATAGCA-3’ located within exon 1 and 2\(^{21}\) were used, together with the fluorescent probe 5’-GATGAAAACCGACGCATAGCA-3’, labeled at the 5’-terminus with the reporter dye Texas red and at the 3’-terminus with the quenching dye. Tenfold lower quantities of β-2M primers and probe with respect to *Leishmania* 18S ones were added to the reaction mixture, to avoid sensitivity of the 18S PCR being affected by competition for β-2M amplification. For the PCR reaction, 1.25 µL of isolated RNA sample was added to 11.25 µL of amplification mix (Bio-Rad iScriptTM One-Step RT-PCR Kit for Probes, Hercules, USA) containing 2X PCR reaction reagent (20 mM Tris-HCl (pH 8.4), 50 mM KCl, 0.8 mM dNTPs, 3 mM MgCl\(_2\) and 0.6 U/µL iTaq DNA polymerase), reverse transcriptase, 0.8 µM of each *Leishmania* primer and 0.2 µM of FAM-MGB probe, 80 nM of each β-2M primer and 20 nM of probe. Amplification and real-time measurement were performed with the CFX-1 Cycler (Bio-Rad) using the following conditions: 10 min at 50°C, 5 min at 95°C followed by 45 cycles, each consisting of 30 s at 95°C and 45 s at 60°C.

Toxicity thresholds for macrophage viability were set according to 90% cytotoxic concentrations (CC\(_{90}\)) of tested drugs, corresponding to a 3 Ct value increase in β-2M amplification over the controls. Consistent reduction of β-2M signal over the triplicate samples and its dose-related dependency from drug concentration confirmed low RNA contents being caused by drug toxicity rather than poor test performance. Inter-replicate variation >3 Ct values for either *Leishmania* 18S or β-2M amplification was considered indicative of poor RNA quality or extraction performance, resulting in the exclusion of these samples.

**Data analysis**

The inhibition of parasite growth was determined by comparing the amount of viable parasites detected in the drug-treated samples with that of the untreated controls. Non-linear regression analysis (Graph-Pad Software Inc., San Diego, USA) was used for curve fitting and calculation of 50% inhibitory concentrations (IC\(_{50}\)). The relationship between the two assays was studied by use of the individual logIC\(_{50}\) values. Correlation between data obtained with the two assays was assessed by the Pearson’s correlation test, while the Bland and Altman plot was used to study the level of agreement between the two methods and to show dispersion of data.\(^{22}\)
Results

**Performance of the duplex qRT-PCR**

The qRT-PCR targeting the *Leishmania* 18S rRNA has previously been validated for quantification of *Leishmania* parasites. The standard curve for amplification was linear over a 6-fold log₁₀ range of *L. donovani* 1S RNA.

In the present study, a dilution series of Trizol®-extracted RNA from *L. donovani* 1S promastigotes was used as a standard for the duplex qRT-PCR in a background of 100 ng of THP-1 cell RNA extract, which corresponds to the average amount of human RNA found in each microtiter well seeded with *Leishmania* amastigotes. The *Leishmania* 18S amplification reaction was confirmed linear with a correlation coefficient of 0.995 over the range of 1 ng to 1 fg RNA, corresponding to 10,000-0.01 parasites (Figure 1A, blue curves, and Figure 1B). To exclude that sensitivity of the *Leishmania* 18S PCR could be negatively affected by competition for β-2M amplification, the standard samples were tested with and without β-2M primers in the PCR mix. Comparison of the two reaction mixes showed equally good amplification of *Leishmania* 18S for all standard samples, with no loss of sensitivity due to competition for β-2M amplification (data not shown). The β-2M mRNA signals derived from amplification of background THP-1 cell RNA in the standard samples were all comparable (Ct values ranging from 23.3 to 23.7), regardless of the amount of *Leishmania* RNA present (Figure 1A, red curves). Only the standard samples with the highest parasite content (1 ng and 100 pg parasite RNA) showed slightly reduced amplifications of β-2M (Ct values of 25.6 and 24.1, respectively), due to internal competition (Figure 1A, red curves 1-2).

**Pharmacological validation**

To validate the use of the qRT-PCR for assessment of drug efficacy against *Leishmania* intracellular amastigotes, the PCR assay was compared with standard microscopy by a blind, side-by-side evaluation. A set of 10 compounds marked

![Figure 1. Duplex qRT-PCR targeting the *Leishmania* 18S rRNA (in blue) and the human β-2-microglobulin mRNA (in red). Amplification curves (A) and linearity range of the *Leishmania* 18S amplification reaction (B) for a dilution series of *Leishmania donovani* 1S RNA ranging from 1 ng (1) to 1 fg (7) in a background of 100 ng of THP-1 cell RNA. Modest reduction of β-2M amplification (red curves 1-2) was observed in the presence of 1 ng and 100 pg of *Leishmania* RNA, respectively.](image-url)
by different potencies and mechanisms of action was used to validate the performance of the duplex qRT-PCR. The compound panel included a series of protein kinase-, protein transporter- and phosphodiesterase-inhibitors.\textsuperscript{19} Next to these compounds, three reference anti-leishmanial drugs were also assessed by the developed assay. A high correlation was found between the parasite load estimated by qRT-PCR and microscopy counting, regardless of which compound and concentration the parasites were exposed to (Figure 2 and Table 1). The IC\textsubscript{50} values yielded by the two assays during two independent experiments showed good agreement for most of the tested compounds (Table 1). Few discrepancies were observed (imipramine, VUF11852 and VUF11856), in which either the qRT-PCR or the microscopy data were marked by poor reproducibility with the replicate experiment. The Pearson’s correlation test confirmed a significant correlation between the logIC\textsubscript{50} values obtained by the two assays ($r = 0.95$, $n = 21$, $P < 0.0001$) (Figure 3A). In the Bland and Altman plot (Figure 3B), the mean difference in the logIC\textsubscript{50} values of the 10 compounds yielded by the qRT-PCR and microscopy was -0.03 (limits of agreement -0.30 and 0.24). No tendency for

The mean Ct value for β-2M amplification ranged from 24.5 in the first experiment to 22.7 in the second experiment for untreated *Leishmania*-harboring macrophages and uninfected cells. When serial dilutions of the test compounds were incubated with the *Leishmania*-infected cells, a dose-related increase in β-2M Ct values could be observed (Figure 4), suggesting reduced viability of macrophages as a result of drug exposure. The cytotoxic effect displayed by these compounds and indicated by an at least 10-fold lower β-2M amplification (corresponding to ≥3 Ct value increase over the controls) corroborated microscopy observation, whereby poor or no cell morphology was confirmed (data not shown). Based on these microscopy observations, a 10-fold lower β-2M amplification was considered indicative of overall cell toxicity.

Figure 3. The estimated mean difference (-0.03) and its confidence interval (± 2 standard deviation) are shown as horizontal lines.
Discussion

In vitro amastigote-based assays for screening of novel anti-leishmanial compounds have been widely recognized as highly predictive of in vivo drug efficacy, although experimental constrains still limit their broad implementation. New technologies for improving the quality of these assays have been developed, including several molecular tools for evaluation of anti-leishmanial drug activities in both in vitro and in vivo models. The present work describes a further advancement of these genetic assays, in which viability of *Leishmania* intracellular forms, the amastigotes, and their host cells is simultaneously assessed by a duplex qRT-PCR, targeting the *Leishmania*-specific 18S rRNA and the human β-2M mRNA, which serves as internal control for test performance and drug cytotoxicity. Pharmacological validation of the assay, performed with a 10-compound set blindly assessed against standard microscopy, resulted in a good correlation between anti-leishmanial dose-response curves obtained by the two assays and the corresponding IC₅₀ values, even when considering the highly subjective and inaccurate nature of microscopy scoring. Duplicate experiments showed fair intra-assay agreement.

Figure 4. Drug dose-response curves of *Leishmania donovani* 1S intracellular amastigotes, as measured by the qRT-PCR assay (closed circles, left y axis) and the corresponding Ct values for β-2M amplification (open rhombus, right y axis). Values indicating *Leishmania* growth (closed circles) are normalized by use of the upper and the lower best-fit values as 100 and 0% responses, respectively. Data are plotted as the means ± standard errors of the means of three replicates for the qRT-PCR assay and two replicates for microscopy. Representative data of one out of two experiments are shown.
for both PCR and microscopy, although for few compounds, a 4- to 5-fold difference in IC50 values was observed, possibly caused by differences in the infection load. Intra-assay variation of parasite burdens is not uncommon when using this amastigote-macrophage model, as parasites need to actively enter the host cells and proliferate therein, upon conversion into amastigotes. This may have important implications for the IC50 outcome, as confirmed by the critical role played by the number of promastigotes used to infect the cells, the particular Leishmania strain they belong to and the cell line bearing the infection.24

Compared to alternative drug screening assays, microscopy counting offers the advantage of enabling host cell morphology to be visualized, so that both anti-leishmanial activity and drug cytotoxicity can be simultaneously assessed. In this respect, this duplex qRT-PCR represents a valuable alternative, as it allows for simultaneous detection of parasite and cell viability. Substantial drug cytotoxicity, microscopically confirmed by the poor morphology of human macrophages, was detected by the qRT-PCR, which yielded an at least ten-fold reduced β-2M amplification rate as opposed to the untreated controls.

Extensive debate on the use of DNA over RNA for drug resistance studies16,20,25 has resulted in the general belief that DNA remains stable over a long period of time, pending on environmental conditions, and it is therefore unsuited for testing viability of micro-organisms, including Leishmania spp. Our preliminary experiments conducted with leishmanicidal doses of amphotericin B indicated that 18S DNA levels of L. donovani 1S-infected macrophages differed less than a factor 10 from the untreated controls (data not shown), whereas a 1000-fold difference in 18S rRNA content was observed when the same samples were assayed by qRT-PCR and microscopy. Though in agreement with the general opinion, these findings contradict what was previously observed by others, who used real-time PCR to amplify DNA extracts and assess anti-leishmanial drug activity. Gomes et al.18 targeted the Leishmania-18S DNA in a Leishmania infantum amastigote-mouse model, obtaining amphotericin B IC50 values (0.02 µM) that corroborate our and previously published results. Whether these data resulted from a comparable reduction in parasite amount, however, is unknown since the report does not mention absolute parasite numbers. Ordóñez-Gutiérrez et al.17 were able to demonstrate by PCR only a 3-fold decrease in Leishmania amastigote DNA content, as opposed to the 10-fold difference observed by microscopy during exposure to cystatin. Finally, Prina et al.26 also used a DNA-based protocol for testing parasite viability and thereby demonstrate that Leishmania DNA is rapidly degraded in vitro following parasite death. These observations, however, were based on the use of L-Leucine methyl ester only, an experimental drug inducing rapid death of Leishmania mexicana and Leishmania amazonensis spp. Commercially available anti-leishmanial drugs, such as those tested in this study, are instead known to act progressively over a longer period of time,4 resulting in potentially different effects on parasite/host cell viability and corresponding metabolisms. Furthermore, the use in the three above-mentioned studies of mouse cells as a macrophage source rather than the human THP-1 cell line employed here, may partially account for the discrepancies observed, given that profound differences between rodent and human macrophages have been described.27
The present study was conducted on a selection of compounds, for which comparable anti-leishmanial activities were obtained by qRT-PCR and microscopy. Further evaluation of the assay is now required to establish its performance with different Leishmania models and testing compounds. Efforts to automatize the technique are also equally crucial to ensure this qRT-PCR may be suitable for high-throughput drug screening. Accurate RNA isolation is key to this assay, but several automated RNA extraction systems capable of yielding high-quality RNA are nowadays available on the market. This opens important avenues for the further development of this assay.

In conclusion, the present results demonstrate the value of this qRT-PCR as a sensitive and reliable tool for assessing drug activities against Leishmania intracellular amastigotes and their host cells, simplifying the use of the clinically relevant stage of leishmaniasis for drug discovery programs.
