Abstract

In this paper two kernel-based nonparametric estimators are proposed for estimating the components of an additive quantile regression model. The first estimator is a computationally convenient approach which can be viewed as a viable alternative to the method of De Gooijer and Zerom (2003). By making use of an internally normalized kernel smoother, the proposed estimator reduces the computational requirement of the latter by the order of the sample size. The second estimator involves sequential fitting by univariate local polynomial quantile regressions for each additive component with the other additive components replaced by the corresponding estimates from the first estimator. The purpose of the extra local averaging is to reduce the variance of the first estimator. We show that the second estimator achieves oracle efficiency in the sense that each estimated additive component has the same variance as in the case when all other additive components were known. Asymptotic properties are derived for both estimators under dependent processes that are strictly stationary and absolutely regular. We also provide a demonstrative empirical application of additive quantile models to ambulance travel times using administrative data for the city of Calgary.

Keywords: Additive models; Asymptotic properties; Dependent data; Internalized kernel smoother; Local polynomial; Oracle efficiency.

1 Introduction

Suppose $Y$ denotes a response variable that depends on the vector of stochastic covariates $X = (X_1, \ldots, X_d)^T$, $d \geq 2$, where $T$ denotes the transpose of a matrix or a vector. We consider the case where the relationship between $Y$ and $X$ follows a quantile regression set-up,

$$Y = Q_\alpha(X) + \mathcal{E}_\alpha,$$

where $Q_\alpha(\cdot)$ is an unknown real-valued function and $\mathcal{E}_\alpha$ is an unobserved random variable that satisfies $\mathbb{P}(\mathcal{E}_\alpha \leq 0 | X = x) = \alpha$ for all $x$ where $0 < \alpha < 1$ is the quantile of interest. Thus, $Q_\alpha(x)$ denotes the conditional quantile of $Y$ given $X = x$. Indeed, there is a large body of literature on the estimation of $Q_\alpha(x)$ and its asymptotic properties (see, e.g., Chaudhuri 1991; Fan, Hu, and Troung 1994). But it is well-known that for high-dimensional covariates (moderate to large value of $d$) nonparametric methods suffer from the curse-of-dimensionality, which does not allow precise estimation of conditional quantiles with reasonable sample sizes. For this reason several authors have proposed dimension reduction techniques. For example, Honda (2004), Kim (2007) and Cai and Xu (2008) consider quantile regression with varying coefficients and Lee (2003) studies conditional quantiles using a partially linear regression model. In this paper, we assume $Q_\alpha(\cdot)$ to be additive of the following form,

$$Q_\alpha(x) = c_\alpha + q_{\alpha,1}(x_1) + \cdots + q_{\alpha,d}(x_d),$$

where $x = (x_1, \ldots, x_d)^T$, $c_\alpha$ is a constant, and $q_{\alpha,u}(x_u)$ ($u = 1, \ldots, d$) are smooth nonparametric functions representing the $\alpha$-th quantile function of $Y$ related only to $X_u$. Additive models are simple, easily interpretable, and sufficiently flexible for many practical applications.

Given observed data on $X$ and $Y$, our interest is to efficiently estimate each additive component $q_{\alpha,u}(x_u)$ in (1.2). This nonparametric estimation problem is first considered by Fan and Gijbels (1996, pp. 296-297) where they suggest a back-fitting procedure (see also Yu and Lu, 2004). Although the back-fitting algorithm is easy to implement, there is no guarantee for convergence and its iterative structure makes it difficult to establish asymptotic results. Doksum and Koo (2000) introduce an easily implementable direct spline method that does not require iterations. But they do not provide asymptotic convergence results. De Gooijer and Zerom (2003) propose a simple direct kernel estimator. Horowitz and Lee (2005) suggest a hybrid step-wise approach where they use a series method in the first step and kernel smoothing in the second step. Both De Gooijer and Zerom (2003), and Horowitz and Lee (2005) provide detailed asymptotic theory.
and show that their respective estimators achieve a univariate nonparametric rate of convergence regardless of the dimension of $X$.

In this paper, we propose two kernel-based estimators for estimating the additive component functions. Our first estimator extends the works of Kim, Linton and Hengartner (1999) and Manzan and Zerom (2005) to the context of conditional quantiles. We show that the proposed estimator is asymptotically normal and converges at the univariate nonparametric optimal rate. This estimator is computationally more attractive than the average quantile estimator of De Gooijer and Zerom (2003) as it reduces the computational requirement of the latter by the order of the sample size ($n$), i.e. $O(n)$. In applications, this computational advantage can be very significant when $n$ is large and/or when implementing computer-intensive methods such as bootstrap or cross-validation. For example, in the empirical analysis of ambulance travel times (see Section 5), we have over 7000 observations. For $n$ of this size, implementing the average quantile estimator requires excessively large computational time. In addition to its computational inconvenience, the average quantile estimator is also not robust to correlated covariates in the sense that its efficiency deteriorates with an increase in the correlation among the covariates $(X_1, \ldots, X_d)$. This is due to the need for smoothing at points that may not lie in the support of the covariate space. In contrast, our estimator is not affected by this problem.

Although the first estimator is practically appealing, its asymptotic variance has an undesirable additional term. To mitigate this efficiency problem, we propose a second estimator that uses additional local averaging. The local averaging involves sequential fitting by univariate local polynomial $\alpha$-quantile regressions for each additive components in (1.2) with the other additive components replaced by the corresponding estimates from the first estimator. The second estimator is also shown to be asymptotically normal and converges at the univariate nonparametric optimal rate. Further, we show that it achieves oracle efficiency where each estimated additive component has the same variance as in the case when all other additive components were known. In terms of computer implementation, this efficient estimator only takes twice as many computational operations as the first estimator. Thus, efficiency is achieved without compromising on computational simplicity. The estimator of Horowitz and Lee (2005) also shares the oracle property.

The asymptotic properties of our two kernel estimators are derived for dependent data. On the other hand, Horowitz and Lee (2005) establish the asymptotic properties of their estimator only
for the case of independent data. Thus, our theoretical results are more general. We assume that the sample \((X_1, Y_1), \ldots, (X_n, Y_n)\) is a strictly stationary weakly dependent data from the population \(\{X, Y\}\). We focus on absolutely regular (or \(\beta\)-mixing) processes. For any \(a < b\), let \(\mathcal{M}_b^a\) denote the sigma algebra generated by \((Z_a, \ldots, Z_b)\) with \(Z_i = (X_i, Y_i)\). A process is called absolutely regular, if, as \(m \to \infty\),

\[
\pi(m) = \sup_{s \in \mathbb{N}} \mathbb{E} \left\{ \sup_{\mathcal{H} \in \mathcal{M}_{s+m}^{\infty}} [\mathbb{P}(\mathcal{H} | \mathcal{M}_{s}^{\infty}) - \mathbb{P}(\mathcal{H})] \right\} \to 0. \tag{1.3}
\]

For more details on \(\beta\)-mixing processes, see, for example, Yoshihara (1978) and Arcones (1998).

The paper is organized as follows. In Section 2 we provide a description of a modified average quantile estimator together with its asymptotic properties. In Section 3, an oracle efficient estimator is introduced and its asymptotic properties are also established. In Section 4, we illustrate the numerical performance of the proposed estimators using simulated data. In Section 5, we provide a demonstrative empirical application of additive quantile modeling to ambulance travel times using administrative data for the city of Calgary. Section 6 provides concluding comments. Technical arguments and proofs are provided in the Appendix.

### 2 A modified average quantile estimator

Here, we introduce our first kernel estimator for the additive component function \(q_{\alpha,u}(x_u)\) \((u = 1, \ldots, d)\) where for identification purposes we assume that \(\mathbb{E}\{q_{\alpha,u}(X_u)\} = 0\). It is also assumed that \(X\) has density denoted by \(f(\cdot)\). For ease of exposition, we denote by \(X_u\) the \(u\)-th element of \(X\) and \(W_u\) the set of all \(X\) variables excluding \(X_u\), i.e. \(W_u = (X_1, \ldots, X_{u-1}, X_{u+1}, \ldots, X_d)^T\). Note that \(X = (X_u, W_u)\). Let \(f_u(\cdot)\) and \(f_w(\cdot)\) denote the density functions of \(X_u\) and \(W_u\), respectively. Following Kim, Linton and Hengartner (1999), we define the function

\[
\Phi(x_u, w_u) = \frac{f_u(x_u)f_w(w_u)}{f(x_u, w_u)}.
\]

It is easy to show that this function has two desirable properties:

\[
\mathbb{E}\{\Phi(X_u, W_u) | X_u = x_u\} = 1 \quad \text{and} \quad \mathbb{E}\{\Phi(X_u, W_u) q_{\alpha,k}(X_k) | X_u = x_u\} = 0 \quad \text{for} \quad k \neq u.
\]

Multiplying each side of equation (1.2) by \(\Phi(\cdot, \cdot)\) and taking conditional expectations conditional on \(X_u = x_u\), we obtain

\[
\mathbb{E}\{\Phi(X_u, W_u) Q_\alpha(X) | X_u = x_u\} = q^{*}_{\alpha,u}(x_u) = c_\alpha + q_{\alpha,u}(x_u), \quad (u = 1, \ldots, d). \tag{2.1}
\]
Therefore, \( q_{u,a}^*(x_u) \) coincides, up to a constant, with the component \( q_{u,a}(x_u) \) of the additive quantile model. Thus, we can estimate \( q_{u,a}(x_u) \) by the following estimator which we call the modified average quantile estimator,

\[
\hat{q}_{u,a}(x_u) = \hat{q}_{u,a}^*(x_u) - \hat{c}_u
\]  

(2.2)

with the two estimators \( \hat{q}_{u,a}^*(x_u) \) and \( \hat{c}_u \) given in (2.4) and (2.3), respectively. Because \( c_u = EQ_u(X) \), we can estimate \( c_u \) by

\[
\hat{c}_u = \frac{1}{n} \sum_{i=1}^{n} \hat{Q}_u(X_i),
\]  

(2.3)

where \( \hat{Q}_u(\cdot) \) is a consistent estimator of \( Q_u(\cdot) \) which is defined in (2.6). Following Jones, Davies and Park (1994), we compute \( \hat{q}_{u,a}^*(x_u) \) as follows,

\[
\hat{q}_{u,a}^*(x_u) = \frac{1}{nh_1} \sum_{i=1}^{n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) \frac{\hat{f}_w(W_{i,u})}{\hat{f}(X_i)} \hat{Q}_u(X_i),
\]  

(2.4)

where \( K(\cdot) \) is a kernel function, \( h_1 \) is a bandwidth (or smoothing parameter) and \( \hat{f}_w(\cdot) \) and \( \hat{f}(\cdot) \) are kernel smoothers of the corresponding densities. Note that, unlike the usual kernel-based conditional expectation smoothers, i.e.

\[
\frac{1}{nf_u(x_u)h_1} \sum_{i=1}^{n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) \Phi(X_{i,u}, W_{i,u}) \hat{Q}_u(X_i),
\]  

(2.5)

(2.4) internalizes the normalizing density \( f_u(\cdot) \) eliminating the need for explicit estimation of \( f_u(x_u) \) (see the denominator in 2.5). When compared to that of De Gooijer and Zerom (2003), this internalization offers a significant practical advantage by reducing computational cost by the order \( n \) (i.e., \( O(n) \)). To better see this advantage, we can re-define (2.4) in a more computationally convenient way as follows. Say, the aim is to estimate \( \hat{q}_{u,a}^*(\cdot) \) at all observation points \( X_{u,i} \) for \( i = 1, \ldots, n \). First, define the following \( n \times n \) smoother matrices,

\[
S_u^e = \left[ \frac{1}{nh_1} K \left( \frac{X_{i,u} - X_{i,a}}{h_1} \right) \right]_{i,l}, \quad S_u^w = \left[ \frac{1}{nh_2^d} L_1 \left( \frac{W_{i,u} - W_{i,a}}{h_2} \right) \right]_{i,l},
\]

\[
S = \left[ \frac{1}{nh_2^d} L_2 \left( \frac{X_{i} - X_{a}}{h_2} \right) \right]_{i,l},
\]

where \( L_1(\cdot) \) and \( L_2(\cdot) \) are two kernel functions, and \( h_2 \) is the bandwidth. Then, we can estimate the \( n \times 1 \) vector of estimates \( (\hat{q}_{u,a}^*(X_{u,1}), \ldots, \hat{q}_{u,a}^*(X_{u,n}))^T \), all at once, as follows

\[
(\hat{q}_{u,a}^*(X_{u,1}), \ldots, \hat{q}_{u,a}^*(X_{u,n}))^T = S_u^e \hat{Q}_u \circ (S_u^w \cdot (S \cdot e)),
\]

where \( \circ \) and \( ./ \) denote matrix Hadamard product and division, respectively, while \( e = (1, \ldots, 1)^T \) and \( \hat{Q}_u=(\hat{Q}(X_1), \ldots, \hat{Q}(X_n))^T \). Further, unlike that of De Gooijer and Zerom (2003), the
computation of \( \tilde{q}^*_u(u) \) does not require smoothing at pairs \((u, W_u)\). This feature is important as \((u, W_u)\) may not lie in the support of \((X_u, W_u)\). Unless the product of the marginal supports is equal to the joint support, we may be estimating at points where the joint density is zero. Many data sets have highly correlated design, which causes the finite support to violate the above requirement. The estimator in (2.4) does not face this problem and hence is robust against correlated design.

Now we define an estimator for \( Q_\alpha(x) \). We assume that \( Q_\alpha(x) \) is \( p \) times \((p \geq 2)\) continuously differentiable in the neighborhood of \( x \in \mathbb{R}^d \). This will allow us to use the well-known local polynomial quantile smoothing; see Honda (2000). For non-negative integer vector \( \lambda = (\lambda_1, \ldots, \lambda_d) \), let \( |\lambda| = \sum_i \lambda_i \) and \( x^\lambda = \Pi x_i^{\lambda_i} \). Also let the vectors \( V_1(\frac{X-x}{h}) \) and \( \beta_x \) be constructed from the elements \( h^{-|\lambda|}(X-x)^\lambda \) and \( h^{-|\lambda|} \partial q_\lambda(x)_{x^\lambda} \), respectively, which are arranged in natural order with respect to \( \lambda \) such that \(|\lambda| \leq p - 1\). Then, we define \( \hat{Q}_\alpha(x) \) by

\[
\hat{Q}_\alpha(x) = e_1^T \hat{\beta}_x ,
\]

where \( e_1 \) is a \( p \)-dimensional unit vector with the first element \( 1 \) and all other elements \( 0 \) and the vector \( \hat{\beta}_x \) minimizes

\[
(nh^d)^{-1} \sum_{i=1}^n \rho_\alpha \left( Y_i - \beta_x^T V_1 \left( \frac{X_i - x}{h} \right) \right) L \left( \frac{x - X_i}{h} \right),
\]

where \( \rho_\alpha(\cdot) \) is a check function that is defined as \( \rho_\alpha(s) = |s| + (2\alpha - 1)s \) for \( 0 < \alpha < 1 \) and \( L(\cdot) \) is a kernel function and \( h \) is the bandwidth. The above local polynomial smoothing can be implemented using the weighted linear quantile regression routine, available in the \texttt{R QUANTREG} library, where the weights are defined through the kernel \( L(\cdot) \).

### 2.1 Asymptotic behavior

Here, We derive the asymptotic behavior of the modified average quantile estimator \( \tilde{q}_{\alpha,u}(u) \) (2.2) under \( \beta \)-mixing dependence assumption (1.3). In this paper, \( C < \infty \) denotes a positive generic constant. We use the following regularity conditions to derive the asymptotic properties.

**C1.** The additive function \( q_{\alpha,u}(u) \) is \( p \) times continuously differentiable in the neighborhood of \( u \in \mathbb{R} \). The full-dimensional conditional quantile \( Q_\alpha(x) \) is also \( p \) times continuously differentiable in the neighborhood of \( x \in \mathbb{R}^d \). The probability density function \( f(x) \) of \( X \) is bounded from above and has \( \hat{p} \)th derivatives on their support set, where \( \hat{p} > \frac{pd}{p+1} \).
C2. Let \( g(y|x) \) be the conditional probability density function of \( E_\alpha \) given \( X = x \). For any \( x \) in the support set of \( X \), it has the first continuous derivative with respect to the argument \( y \) in the neighborhood of 0.

C3. \( K(\cdot) \) is a \( p \)-th order kernel function that satisfies \( \int K(t_1)dt_1 = 1, \int t_1^j K(t_1)dt_1 = 0 \) for \( j = 1, \ldots, p - 1 \) and \( \int t_1^p K(t_1)dt_1 \neq 0 \). For \( i = 1, 2 \), \( L_i(\cdot) \) is a \( \tilde{p} \)-th order kernel function that satisfies \( \int L_i(s)ds = 1, \int s^j L_i(s)ds = 0 \) for \( j = 1, \ldots, \tilde{p} - 1 \) and \( \int s^{\tilde{p}} L_i(s)ds \neq 0 \) with \( s \) in \( d - 1 \) or \( d \) dimensional spaces according to \( L_i(\cdot) \). \( L(t) \) is a second-order kernel which has bounded and continuous partial derivatives of order 1.

C4. i). There exist two constants \( \delta > 2 \) and \( \gamma > 0 \) such that \( \delta > 2 + \gamma \) and the function

\[
\mathbb{E}\left\{ \left| \frac{f_w(W_u)}{f(X)} Q_\alpha(X) \right|^\delta \right| \ X_u = x_u \}
\]

is bounded in the neighbor of \( x_u \).

ii). The mixing coefficients \( \pi(i) = O\left( (i^{-\theta}) \right) \) with \( \theta \geq \max\left\{ p + \frac{4}{p} + 6, \frac{2(p+1)^M}{3-2p} + 1 \right\} \).

C5. i). It holds that \( n^{-\gamma/4} h_1^{(2+\gamma)/\delta-1-\gamma/4} = O(1) \) and \( \limsup_n n h_1^{2p+1} < \infty \).

ii). Assume that there exists a sequence of positive integers \( s_n \) such that \( s_n \to \infty \), \( s_n = o\left( (n h_1)^{1/2} \right) \), and \( (n h_1)^{1/2} \pi(s_n) \to 0 \), as \( n \to \infty \).

iii). For some sufficiently small constant \( \epsilon > 0 \), \( h = C n^{-\kappa} \) with constant \( \kappa \) satisfying \( \frac{1}{2p+1} < \kappa < \frac{2p+3-(2p+1)(1-2\epsilon)}{3d(2p+1)(1+\frac{2}{p^2} - \frac{\theta}{p^2})} \) and \( h/h_1 \to 0 \).

iv). It holds that \( h_1^{\theta(1-\frac{2}{p})} h^{2p-2} \to 0, \ n h^d (h_1 h^d)^{3+\epsilon} \to \infty \) and \( n h_1^{1-1} \left( h_1 h_2^{d-1} \right)^{1+\frac{\epsilon}{p}} \to \infty \) with \( h_2 = C n^{-\frac{1}{p+\epsilon}} \).

C6. For any \( j \geq 1 \), the joint density functions \( (X_1, X_{j+1}) \) are bounded from above.

Let \( \kappa_p = \int t_1^p K(t_1)dt_1 \) and \( \|K\|_2 = \int K^2(t_1)dt_1 \). The following theorem summarizes the asymptotic distribution of \( \hat{q}_{\alpha,u}^*(x_u) \).

**Theorem 2.1.** When the conditions C1 to C6 are met,

\[
\sqrt{n h_1^p} \left( \hat{q}_{\alpha,u}^*(x_u) - q_{\alpha,u}^*(x_u) - \frac{(p)}{q_{\alpha,u}(x_u) \kappa_p h_1^p} \right) \to N \left( 0, \sigma^2 \right) \tag{2.7}
\]

in distribution with \( \sigma^2 = \sigma_1^2 + \sigma_2^2 \) where

\[
\sigma_1^2 = \frac{\alpha(1 - \alpha)}{f_u(x_u)} \frac{\|K\|_2^2}{\mathbb{E}\left\{ \frac{\Phi^2(X)}{g^2(0|X)} \right| X_u = x_u} \end{align}

\[
\sigma_2^2 = \frac{\|K\|_2^2}{\mathbb{E}\left\{ \Phi^2(X) Q_\alpha^2(X) \right| X_u = x_u} \end{align}

\]
Remark 1. From Theorem 2.1, the optimal bandwidth that minimizes the asymptotic mean squared error (AMSE) is given by,

\[ h_{1}^{\text{opt}} = \left( \frac{p! \sigma}{q_{\alpha,u}(x_u) \kappa_p} \right)^{\frac{2}{p+1}} n^{-\frac{1}{2p+1}}. \]

Remark 2. Although the asymptotic variance \( \sigma^2 \) cannot be directly compared to the corresponding variance of the estimator of De Gooijer and Zerom (2003), there is a visible additional term (\( \sigma^2_2 \)) in the case of our estimator. A similar problem has also been shown by Kim, et al. (1999) for the conditional mean case. This motivates us to introduce our second estimator (see Section 3) whose goal is to mitigate this efficiency problem without compromising on bias.

Proposition 2.2. Under the conditions of Theorem 2.1,

\[ \hat{c}_a - c_a = o_{\mathbb{P}} \left( n^{-\frac{p}{2p+1}} \right). \]  

(2.8)

Corollary 2.3. Under the conditions of Theorem 2.1, if we choose \( h_1 = h_1^{\text{opt}} \), then it holds that

\[ \left( \frac{p! \sigma}{q_{\alpha,u}(x_u) \kappa_p} \right)^{\frac{1}{2p+1}} n^{\frac{p}{2p+1}} \left( \hat{q}_{\alpha,u}(x_u) - q_{\alpha,u}(x_u) - \frac{q_{\alpha,u}(x_u) \kappa_p}{p!} n^{-\frac{1}{2p+1}} \right) \rightarrow N \left( 0, \sigma^2 \right) \]

in distribution.

3 Oracle efficient estimator

In Section 2 we introduced a modified average quantile estimator and show that it estimates the additive components at a one-dimensional nonparametric optimal rate regardless of the size of \( d \). However, a closer look at Theorem 2.1 indicates that the asymptotic variance includes a second term (\( \sigma^2_2 \)) which inflates the value of the variance. To deal with this inefficiency, we extend the idea of Linton (1997) and Kim et al (1999) to the quantile context and suggest a second estimator that involves sequential fitting of univariate locally polynomial quantile regressions for each of the additive components in (1.2) with the other additive components replaced by the corresponding estimates from the average quantile estimator. In fact, we will show in Section 3.1 that the proposed estimator is oracle efficient in the sense that it is asymptotically distributed with same variance as it would have if the other additive components were known. Importantly, this efficient
estimator only takes twice as many computational operations as the modified average quantile estimator. Thus, efficiency is achieved without compromising on computational simplicity.

We construct this estimator as follows. First, define

$$
\hat{Q}^*_{\alpha,-u}(W_u) = \hat{q}^*_{\alpha,1}(X_1) + \cdots + \hat{q}^*_{\alpha,u-1}(X_{u-1}) + \hat{q}^*_{\alpha,u+1}(X_{u+1}) + \cdots + \hat{q}^*_{\alpha,d}(X_d),
$$

(3.1)

where $\hat{q}^*_{\alpha,j}(\cdot)$ ($j \neq u$) are the additive estimates from (2.4). For technical convenience, we consider the one-leave-out versions of these first-stage estimates. Let

$$
Y^*_i = Y_i + (d - 2)\hat{c}_\alpha - \hat{Q}^*_{\alpha,-u}(W_{i,u})
$$

where $\hat{c}_\alpha$ is given by (2.3). Also let the function $V(t)$ denote a $p$-dimensional vector where its $j$th element is given by $t^{j-1}$. Because $q_{\alpha,u}(x_u)$ is $p$ times continuously differentiable in the neighborhood of $x_u \in \mathbb{R}$, we use local polynomial smoothing to define the oracle efficient estimator as follows

$$
\hat{q}^*_{\alpha,u}(x_u) = e_1^T \hat{\beta}_{x_u},
$$

(3.2)

where $e_1$ is a $p$-dimensional unit vector with the first element 1 and all other elements 0 and the vector $\hat{\beta}_{x_u}$ minimizes

$$
(nh_e)^{-1} \sum_{i=1}^{n} \rho_\alpha \left( Y^*_i - \beta_{x_u}^T V \left( \frac{x_u - X_{i,u}}{h_e} \right) \right) K_e \left( \frac{x_u - X_{i,u}}{h_e} \right),
$$

(3.3)

where $K_e(\cdot)$ is a kernel function and $h_e$ is the bandwidth.

### 3.1 Asymptotic behavior

We investigate asymptotic distribution of $\hat{q}^*_{\alpha,u}(x_u)$ (3.2). To derive our results, we use the following extra regularity conditions.

**C7.** $K_e(t_1)$ is a second-order kernel which has bounded and continuous first order derivative.

**C8.** Let $g_u(t|x_u)$ be the conditional probability density function of $\mathcal{E}_u$ given $X_u = x_u$. For any $x_u$ in the support of $X_u$, it has bounded derivative with respect to the argument $t$ in the neighborhood of 0.

**C9.** It holds that $h_e = Cn^{-\frac{1}{p+1}}$ and the bandwidth of the modified average quantile estimator satisfies that $h_1 = h_en^{-\frac{1}{p+1}}$ with some constant $\varepsilon_0 > 0$ which sufficiently small.
The oracle estimator

Before we provide the asymptotic distribution of \( \hat{q}_{\alpha,u}^\epsilon(x_u) \), we first present results for an oracle estimator which we denote by \( \hat{q}_{\alpha,u}^{\text{oracle}}(x_u) \). Let,

\[
Q_{\alpha,-u}(W_u) = q_{\alpha,1}(X_1) + \cdots + q_{\alpha,u-1}(X_{u-1}) + q_{\alpha,u}(X_u) + \cdots + q_{\alpha,d}(X_d),
\]

where \( q_{\alpha,j}(\cdot) (j \neq u) \) are the true additive components. Because \( q_{\alpha,u}(x_u) \) has \( p \)th derivative and

\[
\alpha = \mathbb{P} \{ Y_i - c_\alpha - Q_{\alpha,-u}(W_{i,u}) \leq q_{\alpha,u}(X_{i,u})|X_{i,u} \},
\]

we use local polynomial smoothing to define \( \hat{q}_{\alpha,u}^{\text{oracle}}(x_u) \) as,

\[
\hat{q}_{\alpha,u}^{\text{oracle}}(x_u) = e_1^T \beta_{x_u}^{\text{oracle}},
\]

where the vector \( \beta_{x_u}^{\text{oracle}} \) minimizes

\[
(nh_\epsilon)^{-1} \sum_{i=1}^n \rho_\alpha \left( Y_i - c_\alpha - Q_{\alpha,-u}(W_{i,u}) - \beta_{x_u}^T V \left( \frac{x_u - X_{i,u}}{h_\epsilon} \right) \right) K_\epsilon \left( \frac{x_u - X_{i,u}}{h_\epsilon} \right).
\]

Note that the oracle estimator is defined in the same way as \( \hat{q}_{\alpha,u}^\epsilon(x_u) \) (see 3.2) except that it uses true values of the other additive components and \( c_\alpha \).

For this oracle estimator, it can be shown that

\[
\sqrt{nh_\epsilon} \left( \hat{q}_{\alpha,u}^{\text{oracle}}(x_u) - q_{\alpha,u}(x_u) - h_\epsilon \frac{p}{p!} \hat{q}_{\alpha,u}^{(p)}(x_u) \frac{1}{p!} e_1^T B^{-1} K_\epsilon \right) \rightarrow N \left( 0, \sigma_0^2 \right),
\]

where \( K_\epsilon = \int t_1^n V(t_1) K_\epsilon(t_1) dt_1, B = \int V(t)V^T(t)K_\epsilon(t)dt \) and

\[
\sigma_0^2 = \frac{\alpha(1-\alpha)}{q_{\alpha,u}^2(0|x_u)f_u(x_u)} e_1^T B^{-1} \int V(t)V^T(t)K_\epsilon^2(t)dt B^{-1} e_1.
\]

The oracle efficient estimator

Now, we show that our estimator \( \hat{q}_{\alpha,u}^\epsilon(x_u) \) (3.2) behaves analogously to the oracle estimator \( \hat{q}_{\alpha,u}^{\text{oracle}}(x_u) \) above. Let \( r_n = n^{\epsilon_0}/\sqrt{nh_\epsilon} \) with \( \epsilon_0 \) being a sufficiently small positive constant. For \( |t_{i,n}| \leq Cr_n, (i = 1, \ldots, n) \), let \( t_n = (t_{1,n}, \ldots, t_{n,n})^T \). Denote by \( V_{u,i} = V \left( \frac{X_{i,u} - x_u}{h_\epsilon} \right) \),

\[
K_{u,i} = K_\epsilon \left( \frac{X_{i,u} - x_u}{h_\epsilon} \right)
\]

and

\[
\hat{\beta}_{t_n} = \arg \min_a \frac{1}{nh_\epsilon} \sum_{i=1}^n K_{u,i} |Y_i - c_\alpha - Q_{\alpha,-u}(W_{i,u}) - a^T V_{u,i} - t_{i,n}|.
\]
Proposition 3.1. Under the conditions C1 to C9, with probability one, it holds uniformly for 
\( |t_{i,n}| \leq C r_n \), \( i = 1, 2, \ldots, n \), that
\[
\hat{\beta}_{t_n} - \hat{\beta}_{\text{oracle}}^t = \frac{B_n^{-1} \mathbb{E}(K_{u,i}V_{u,i}g_u(0|X_{i,u}))}{n h_e} \sum_{i=1}^n t_{i,n} + O \left( \frac{n^{-\epsilon_0}}{\sqrt{n h_e}} \right),
\]
where \( \hat{\beta}_{\text{oracle}}^t \) is as defined in (3.5) and \( B_n = \frac{1}{n} \mathbb{E} K_{u,i}g_u(0|X_{i,u})V_{u,i}V_{u,i}^T \).

Theorem 3.2. Under the conditions C1 to C9, it holds that
\[
\sqrt{n h_e} \left( \hat{q}_{\alpha,u}(x_u) - q_{\text{oracle}}(x_u) \right) = o_P(1).
\] (3.8)

From Theorem 3.2, we see that \( \hat{q}_{\alpha,u}(x_u) \) is asymptotically normally distributed with same mean and variance as \( q_{\text{oracle}}(x_u) \). Therefore, our proposed estimator \( \hat{q}_{\alpha,u}(x_u) \) is oracle efficient.

4 A simulated example

In this section, we provide the finite sample performance of our oracle efficient estimator (denoted in this section by OEE) vis-à-vis two alternative kernel estimators: the estimator of De Gooijer and Zerom (2003) (denoted as DGZ) and the back-fitting approach. We do not include the hybrid estimator of Horowitz and Lee (2005) in our comparison. But we think that the estimator of Horowitz and Lee (2005) will have a similar performance as ours at least for the i.i.d. data case. We use the standard normal density for all kernel functions: \( K_1(\cdot) \), \( K_2(\cdot) \), \( K(\cdot) \), and \( K_e(\cdot) \). These choices are consistent with the assumptions used to derive the asymptotic properties. As in DGZ, we assume the following data generating process,
\[
Y_i = Q_\alpha(X_{i,1}, X_{i,2}) + 0.25 \mathcal{E}_{\alpha,i},
\] (4.1)
where the errors \( \mathcal{E}_{\alpha,i} \) are i.i.d. \( N(0,1) \) and the covariates \( X_1 \) and \( X_2 \) are bivariate normal with zero mean, unit variance, and correlation \( \gamma \). We consider \( \alpha = 0.5 \) (the case of conditional median), correlations \( \gamma = 0.2 \) (low correlation between covariates), 0.8 (high correlation) and sample sizes \( n = 100, 200, 400 \) and 800. The conditional median of \( Y \) is assumed to be additive,
\[
Q_{0.5}(x_1, x_2) = q_{0.5,1}(x_1) + q_{0.5,2}(x_2)
\]
\[
= 0.75x_1 + 1.5\sin(0.5\pi x_2).
\]

We simulate model (4.1) 41 times and in each simulation the three approaches are used to compute the additive median functions \( q_{0.5,1}(\cdot) \) and \( q_{0.5,2}(\cdot) \). To avoid the sensitivity of the
performance of the compared approaches on bandwidth selection, we use the bandwidth values
used in DGZ, although these values may not be optimal. To compute the oracle efficient median
estimates: \( \hat{q}_{0,5,1}^{\gamma}(x_1) \) and \( \hat{q}_{0,5,2}^{\gamma}(x_2) \) (see (3.2)), we need values for \( \hat{Q}_{n,-1}^{\gamma} \) and \( \hat{Q}_{n,-2}^{\gamma} \) (see (3.1)).
The latter two require \( \hat{q}_{0,5,1}^{\gamma}(x_1) \) and \( \hat{q}_{0,5,2}^{\gamma}(x_2) \) (see (2.4)), which in turn depends on \( \hat{Q}_{0.5}(x_1, x_2) \)
(see (2.6)). Thus, we need different bandwidth values at various stages. Instead of a single
value, we let \( h \) (used for \( \hat{Q}_{0.5}(x_1, x_2) \)) vary with the variability of the covariates in the following
way. For smoothing in the direction of \( X_1 \), \( h = 3s_1n^{-1/5} \) and for smoothing in the direction of
\( X_2 \), \( h = s_2n^{-1/5} \) where \( s_k \) is the sample standard deviation of \( X_k \) (\( k = 1, 2 \)). We also need to
choose \( h_1 \) and \( h_2 \). We use \( \{h_1 = 3s_1n^{-1/5}, h_2 = s_2n^{-1/5}\} \) for \( \hat{q}_{0,5,1}^{\gamma}(x_1) \) and \( \{h_1 = s_2n^{-1/5}, h_2 = 3s_1n^{-1/5}\} \) for \( \hat{q}_{0,5,2}^{\gamma}(x_2) \). Finally, we take \( h_c = h \).

Table 1: The average absolute deviation errors (AADE) of the estimated additive components.

We compare our median estimates \( \hat{q}_{0,5,1}^{\gamma}(x_1) \) and \( \hat{q}_{0,5,2}^{\gamma}(x_2) \) (OEE) with DGZ and the back-
fitting approach. The three approaches are compared based on the average absolute deviation
error (AADE). First, the absolute deviation error (ADE) for each estimated function \( \hat{q}_{0,5,k}^{\gamma}(\cdot) \),
\( k = 1, 2 \) is computed at each replication \( j \), i.e. \( ADE_j(k) = \text{Average}[|\hat{q}_{0.5,k}(X_{i,k}) - q_{0.5,k}(X_{i,k})|]_i^n \)
\( (j = 1, \ldots, 41; k = 1, 2) \) where the average is only taken for \( X_k \in [-2, 2] \), to avoid data sparsity.
Then, the AADE is defined as the average of the ADE over the 41 replications. In Table 1, we
report the AADE values by changing \( \gamma \) and/or \( n \).

When \( \gamma = 0.2 \) and \( n \leq 200 \), the OEE is significantly more accurate than DGZ. While the
performance of the three estimators improves with increasing sample size, the OEE maintains
its superiority at all sample sizes. For \( \gamma = 0.8 \), the performance of the three estimators decreases
although the OEE still achieves a decent accuracy at all sample sizes especially for the estimation of \(q_{0.5,1}(\cdot)\). The DGZ is highly inaccurate even at sample sizes as large as \(n = 800\). Although the back-fitting approach tends to converge a lot faster than DGZ, its accuracy is still worse than OEE. From the above simulation experiment, we observe that the OEE is not only a superior approach when compared to existing kernel approaches, it is also robust against highly correlated covariates. For large sample sizes, the back-fitting approach tends to be competitive against OEE. One advantage of the OEE is that it is computed in two easy and fast steps with guaranteed convergence while the back-fitting is iterative and convergence is not assured.

5 Additive models for ambulance travel times

The most common performance measure of emergency medical service (EMS) operations is the fraction of calls with a response time below one or more thresholds. For instance, reaching 90% of urgent urban calls in 9 minutes is a common target in North America and the National Health Service in the U.K. sets targets of 75% in 8 minutes and 95% in 14 minutes for urgent urban calls (Budge, Ingolfsson and Zerom, 2008). Note that these performance targets correspond to quantiles of the response time distribution. Budge et al. (2008) introduce the following semi-parametric model to predict the travel time (travel time of an ambulance to the scene of an emergency is typically the largest component of response time) distribution of high-priority calls for the city of Calgary, Canada,

\[
Y_i = \mu(X_{1,i}, X_{2,i})e^{(\sigma E_{\alpha,i})}, \quad (i = 1, \ldots, n),
\]

where \(i\) denotes a 911 call, \(Y\) denotes travel time and the two predictors \(X_1\) and \(X_2\) are network distance and time-of-day, respectively. The error \(E_{\alpha,i}\) follows a standard \(t\)-distribution with \(\tau\) degrees of freedom, i.e. \(E_{\alpha,i} \sim t_{\tau}(0,1)\) and \(\sigma\) is a scaling parameter. Under this set-up, the function \(\mu(x_1, x_2)\) represents the conditional median of \(Y\) given \((X_1, X_2) = (x_1, x_2)\). In 2003, Calgary EMS responded to \(n = 7457\) high priority calls that involves heart problems, breathing problems, traffic accident, building fire, unconsciousness, house fire, fall, convulsions and seizures, hemorrhage and lacerations, traumatic injuries, and unknown problem.

Budge et al. (2008) assume that the conditional median of travel time to be additive,

\[
\mu(x_1, x_2) = \mu_0 + \mu_1(x_1) + \mu_2(x_2), \quad (5.2)
\]

where \(\mu_0\) is a constant and no parametric form is imposed on the functions \(\mu_1(x_1)\) and \(\mu_2(x_2)\) except that they should be arbitrary twice continuously-differentiable. With (5.2), the travel
time distribution can be fully characterized by conditional quantiles as follows,

\[ Q_\alpha(X_{1,i}, X_{2,i}) = [\mu_0 + \mu_1(X_{1,i}) + \mu_2(X_{2,i})]e^{(\sigma Q_\alpha(\tau))}, \]  

(5.3)

where \( Q_\alpha(x_1, x_2) \) denotes the \( \alpha \)-th conditional quantile of \( Y \) given \( (X_1, X_2) = (x_1, x_2) \) and \( Q_\alpha(\tau) \) is the \( \alpha \)-th quantile of a \( t_{\tau}(0, 1) \)-distribution. Note that, under the above model set-up, the \( \alpha \)-th conditional quantile of travel time at all \( \alpha \) is in fact additive, i.e.,

\[ Q_\alpha(X_{1,i}, X_{2,i}) = c_\alpha + q_{\alpha,1}(X_1) + q_{\alpha,2}(X_2), \]  

(5.4)

where \( c_\alpha = \mu_0 e^{(\sigma Q_\alpha(\tau))} \), \( q_{\alpha,1}(x_1) = \mu_1(x_1) e^{(\sigma Q_\alpha(\tau))} \) and \( q_{\alpha,2}(x_2) = \mu_2(x_2) e^{(\sigma Q_\alpha(\tau))} \).

Motivated by the additive conditional quantile set-up (5.4), our aim is to compare our oracle efficient estimates of the additive quantiles and the corresponding estimates from the semi-parametric approach. It should be noted that the paper of Budge et al. (2008) has a much wider scope and our aim here is only illustrative. Although limited in scope, this example serves two purposes. First, we illustrate how to implement our estimator in practice with a novel data set. Second, we use our estimates to validate, albeit indirectly, the distributional assumption of the semi-parametric model. Although both the semi-parametric approach and the non-parametric approach rely on an underlying additive structure, the non-parametric estimator does not impose an assumption on the distribution of the travel time and hence is more general. We consider three quantile levels \( \alpha = 0.25, 0.5 \) and 0.75. In the estimation of the additive median components (\( \mu_1(\cdot) \) and \( \mu_2(\cdot) \)) for the semi-parametric model, we use cubic smoothing splines with degrees of freedom chosen via minimization of Akaike’s information (AIC) criterion. All unknown components of the semi-parametric model are estimated using the penalized maximum likelihood algorithm of Rigby and Stasinopoulos (2005) which is readily available in the \textit{R} library GAMLSS.

To implement our oracle efficient estimator, we need to select bandwidth values. As in Section 4, we assume that the bandwidth values used to estimate \( \hat{q}_{\alpha,u}^* \) are the same as those for estimating \( \hat{q}_{\alpha,u}^c \). But, at the same time, to allow varying level of smoothness for the two additive quantile functions (corresponding to distance and time-of-day), we adopt separate bandwidth values. So, for each quantile level \( \alpha \), we select two bandwidth values using a rule-of-thumb suggested by Fan and Gijbels (1996) and also adopted by Horowitz and Lee (2005). As an alternative one may also use the data-driven bandwidth selection method by Yu and Lu (2004). We obtain the following bandwidth values for smoothing in the direction of \( X_1 \) (distance): 0.58 (\( \alpha = 0.5 \)), 0.62
(α = 0.25), and 0.65 (α = 0.75). Similarly, for smoothing in the direction of \(X_2\) (time-of-day), the selected bandwidth values are 1.13 (α = 0.5), 1.29 (α = 0.25), and 1.06 (α = 0.75). We use the standard normal density for all kernel functions: \(K_1(\cdot), K_2(\cdot), K(\cdot),\) and \(K_2(\cdot).\)

In Figure 1 we plot the conditional median estimates for both our estimator and the semi-parametric approach. Those in panel (a) and panel (c) correspond to our median estimates corresponding to distance \((X_1)\) and time-of-day \((X_2)\), respectively. The confidence intervals (at the 95% level) for both median estimates are based on the asymptotic variance given in equation (3.7) although we do not do any bias correction. The unknown components of the asymptotic variance are calculated using kernel estimates. On the other hand, panel (b) and panel (d) show the estimated median functions \(\hat{\mu}_1(x_1)\) and \(\hat{\mu}_2(x_2)\) from the semi-parametric method. Comparing the corresponding median estimates from the two approaches, it is interesting to see that both produce closely similar estimated functions. The only difference is that our estimates are not as smooth. In Figure 2 we plot the estimated additive conditional quantile functions for \(\alpha = 0.25\) (panels (a) and (b)) and for \(\alpha = 0.75\) (panels (c) and (d)). Solid lines correspond to our estimates and dashed lines to the semi-parametric approach. Note that the general shape of both quantile functions is similar to those of the median for both distance and time-of-day. As in the case of median, the estimates from the proposed approach are less smooth. It is also interesting to see that the estimated quantiles from both approaches are very close although they seem to differ slightly in their estimated peaks. It should be noted that quantile estimates of the semi-parametric approach are functions of the estimated medians \(\hat{\mu}_1(\cdot)\) and \(\hat{\mu}_2(\cdot)\) as well as \(\hat{\sigma}\) and \(\hat{\tau}\). We find that \(\hat{\sigma} = 0.24\) and kurtosis \(\hat{\tau} = 3.35\) where the latter estimate indicates leptokurtosis in travel times due to infrequently occurring large travel times. Given that the semi-parametric conditional quantile estimates mimics the distribution-free conditional quantile estimates (based on our approach), we may conclude that the conditional distribution of travel time is leptokurtic and the student \(t\)-distribution is a reasonable way to capture it.

For a complete discussion of the practical implications of the conditional quantile modeling of ambulance travel times to operational planning and related decision problems, we refer the reader to Budge et al. (2008). These authors also discuss the additive median function estimates in the context of existing operations research models.
6 Concluding remarks

We have introduced two simple kernel estimators for estimating additive components of an additive quantile regression model. Taken together, these estimators are offered as a better alternative to existing kernel-based methods (De Gooijer and Zerom, 2003 and Yu and Lu, 2004) due to better efficiency and computational convenience. We provide asymptotic properties for both estimators. The validity of the asymptotic properties is established for dependent data and in particular for $\beta$-mixing processes, that include independent and time series data as special cases. In contrast, the asymptotic validity of Horowitz and Lee (2005) is proved only for independent data.

It is well known that proper choice of the bandwidth is critical for the accuracy of any non-parametric function. This paper does not address this issue for the proposed non-parametric estimators. In practice, it is desirable to have a feasible data-driven method of choosing bandwidth values. For example, Yu and Lu (2004) suggest a simple practical bandwidth selection rule for their back-fitting approach. We defer this important topic for future research.

Acknowledgments

We would like to thank the Editor, Associate Editor and the referee for their very helpful comments and suggestions. We also thank the Calgary Emergency Medical Service Department for access to data. Supporting information

The derivations of some intermediate results that are used in the proof of Theorem 2.1 as well as complete proofs of Proposition 2.2, Proposition 3.1 are available as supporting information in the online supplement to this paper. The online supplement also provides a number of important lemmas that are used in the derivations of the theorems and propositions.
Appendix

Here, we provide the proofs for Theorem 2.1 and Theorem 3.2. In the course of the proofs we will refer to results that can be found in the online supplement to this paper.

Proof of Theorem 2.1

We note that \( \hat{q}^*_\alpha (x_u) - q^*_\alpha (x_u) = S_{1,n} + S_{2,n} + S_{3,n} \), where

\[
S_{1,n} = \frac{1}{n h_1} \sum_{i=1}^{n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) \frac{\hat{f}_w (W_{i,u})}{f(X_i)} \left( \hat{Q}_\alpha (X_i) - Q_\alpha (X_i) \right),
\]

\[
S_{2,n} = \frac{1}{n h_1} \sum_{i=1}^{n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) \left( \frac{\hat{f}_w (W_{i,u}) - f_w (W_{i,u})}{f(X_i)} \right) Q_\alpha (X_i)
\]

and \( S_{3,n} = \frac{1}{n} \sum_{i=1}^{n} \zeta_i - q^*_\alpha (x_u) \) with

\[
\zeta_i = \zeta_i (x_u) = \frac{1}{h_1} K \left( \frac{x_u - X_{i,u}}{h_1} \right) \frac{f_w (W_{i,u}) Q_\alpha (X_i)}{f(X_i)}.
\]

To simplify notations, let

\[
\eta_{ij} = K \left( \frac{x_u - X_{i,u}}{h_1} \right) \frac{f_w (W_{i,u})}{f(X_i)} e^T_{ij} B_{i,n}^{-1} L_j V_{j,i} (\alpha - \mathbb{I} (E_{\alpha,j} \leq 0)),
\]

\[
\phi_j \equiv \phi_j (x_u) = \mathbb{E}_j \eta_{ij}
\]

and

\[
\bar{\zeta}_i = h_1^\frac{1}{2} (\zeta_i - \mathbb{E} \zeta_i),
\]

where the notations \( B_{i,n}, L_{ji} \) and \( V_{ji} \), and the operator \( \mathbb{E}_j \) can be referred to Lemma 4 in the online supplementary material. We claim that

\[
\frac{1}{\sqrt{n}} \sum_{i=1}^{n} \bar{\zeta}_i \rightarrow N(0, \sigma_2^2),
\]

\[
S_{2,n} = o_p \left( (nh_1)^{-\frac{1}{2}} \right),
\]

\[
\sqrt{nh_1} \cdot \frac{n-1}{n^2 h_1 h_d} \sum_{j=1}^{n} \phi_j \rightarrow N \left( 0, \sigma_1^2 \right),
\]

\[
S_{1,n} = \frac{n-1}{n^2 h_1 h_d} \sum_{j=1}^{n} \phi_j + o_p \left( \frac{1}{\sqrt{nh_1}} \right).
\]
Proofs of the relationships (A.2) to (A.5) are available in the online supplementary material. Using (1.2), C1, variable substitution and Taylor expansion, we obtain
\[
\begin{align*}
\mathbb{E}\zeta_i &= \int K(t_u)Q_{\alpha}(x_u + h_1t_u, w_u) f_{w}(w_u) dt_u dw_u = c_{\alpha} + \int K(t_u)q_{\alpha,u}(x_u + h_1t_u)dt_u \\
&= q_{\alpha,u}(x_u) + \frac{q_{\alpha,u}^{(p)}(x_u)}{p!}\kappa_p h_1^p + o(h_1^p). \\
&= c_{\alpha} + \int K(t_u)q_{\alpha,u}(x_u + h_1t_u)dt_u
\end{align*}
\]  
(A.6)

Thus, it follows from (A.2) and (A.6) that
\[
\sqrt{n h_1} \left( S_{3,n} - \frac{q_{\alpha,u}(x_u)\kappa_p h_1^p}{p!} \right) \rightarrow N(0, \sigma_2^2).
\]  
(A.7)

From the foregoing results, it can be observed that
\[
\frac{1}{n h_1^{1/2}} \sum_{i=1}^{n} \zeta_i \quad \text{and} \quad \frac{n - 1}{n^2 h_1 h^d} \sum_{i=1}^{n} \phi_i
\]
are the two leading terms of the sum
\[
S_{1,n} + S_{2,n} + S_{3,n}.
\]

For any \(1 \leq i, j \leq n\), it can be noted that \(\text{cov} \left( \zeta_i, \phi_j \right) = 0\). Thus, the two leading terms are asymptotically uncorrelated. All other terms in the sum are asymptotically negligible and convergence at the rate of \(o_P \left( \frac{1}{\sqrt{Nh_1}} \right)\).

In view of the above arguments, (A.3), (A.4), (A.5) and (A.7), the asymptotic normal result in (2.7) holds.

\[ \square \]

**Proof of Theorem 3.2**

Note that
\[
\hat{Q}_{\alpha,-u}(W_{i,u}) - Q_{\alpha,-u}(W_{i,u}) = \sum_{1 \leq j \neq u \leq d} [\hat{q}_{\alpha,j}(X_{i,j}) - q_{\alpha,j}(X_{i,j})].
\]

We now consider the asymptotic representation of \(q_{\alpha,j}^*(X_{i,j}) - q_{\alpha,j}(X_{i,j})\) for \(j \neq u\). By following the same arguments as in the proofs of Theorem 2.1 and also applying Lemma 2 in the online supplement, we obtain three leading terms of \(\hat{q}_{\alpha,j}^*(X_{i,j})\), i.e.,
\[
\frac{q_{\alpha,u}^{(p)}(X_{i,j})}{p!}\kappa_2 h_1^p, \quad \frac{1}{n} \sum_{1 \leq k \neq i \leq n} \psi_k(X_{i,j}) \quad \text{and} \quad \frac{n - 1}{n^2 h_1 h^d} \sum_{j=1}^{n} \phi_j(X_{i,a})
\]
where \(\psi_k(x_j) = \zeta_k(x_j) - \mathbb{E}\zeta_k(x_j)\). Let \(\eta_{i,k} = \sum_{1 \leq j \neq u \leq d} \psi_k(X_{i,j})\) and
\[
\xi_i = \frac{\kappa_2 h_1^p}{p!} \sum_{1 \leq j \neq u \leq d} q_{\alpha,u}^{(p)}(X_{i,j}) + \frac{1}{n} \sum_{1 \leq k \neq i \leq n} \eta_{i,k} + \frac{n - 1}{n^2 h_1 h^d} \sum_{j=1}^{n} \phi_j(X_{i,a}) = \xi_1 + \xi_2 + \xi_3. \quad \text{(A.8)}
\]
Thus, we know, with probability one that
\[
\hat{Q}_{\alpha,u}^*(W_{i,u}) - Q_{\alpha,u}^*(W_{i,u}) = \xi_i + O \left( (n^{1+\epsilon_0}h_1)^{-\frac{1}{2}} \right).
\] (A.9)

For \( \beta \in \mathbb{R}^p \), let \( f_1(\beta) \) be equal to (3.3) with \( \beta_{x,u} \) replaced by \( \beta \), i.e.,
\[
f_1(\beta) = \frac{1}{nh_e} \sum_{i=1}^{n} K_{u,i} \rho_\alpha \left( Y_i + (d-2)\hat{c}_\alpha - \hat{Q}_{\alpha,u}^*(W_{i,u}) - \beta^T V_{u,i} \right),
\]
and
\[
f_2(\beta) = \frac{1}{nh_e} \sum_{i=1}^{n} K_{u,i} \rho_\alpha \left( Y_i - c_\alpha - Q_{\alpha,u}^*(W_{i,u}) - \beta^T V_{u,i} \right),
\]
\[
f_3(\beta) = \frac{1}{nh_e} \sum_{i=1}^{n} K_{u,i} \rho_\alpha \left( Y_i + (d-2)c_\alpha - Q_{\alpha,u}^*(W_{i,u}) - \xi_i - \beta^T V_{u,i} \right).
\]
Let \( \hat{\beta}_3 = \arg \min_\beta f_3(\beta) \). By slight change of the proof of Proposition 2.2 (see online supplement), we can obtain that \( \hat{c}_\alpha - c_\alpha = o_P \left( \frac{n^{-\frac{3}{4}}}{\sqrt{nh_e}} \right) \). Then, using (A.9), it can be inferred that
\[
\sup_{\beta} \left| f_1(\beta) - f_3(\beta) \right| = O_P \left( \frac{n^{-\frac{3}{4}}}{\sqrt{nh_e}} \right).
\]

Combining this and the fact that both \( f_1(\beta) \) and \( f_3(\beta) \) are linear functions leads to
\[
\sqrt{nh_e} \left( \hat{\beta}_{x,u} - \hat{\beta}_3 \right) = O_P \left( n^{-\frac{3}{4}} \right).
\] (A.10)

Note that \( \xi_{i,1} = O(h_1^p) = o(r_n) \) holds with probability one and uniformly for \( 1 \leq i \leq n \). According to SLLN, it can be inferred that \( \xi_{i,2} = O \left( n^{\epsilon_0/4}(nh_1)^{-\frac{1}{2}} \right) = o(r_n) \) holds uniformly for \( 1 \leq i \leq n \), and so does for \( \xi_3 \). Thus, \( \xi_i = o(r_n) \) holds with probability one and uniformly for \( 1 \leq i \leq n \). Thus, using Proposition 3.1 (see online supplement for the proof), we obtain that
\[
\hat{\beta}_3 - \hat{\beta}_{x,u} = \frac{B^{-1/2} \mathbb{E} (K_{2,i}V_{u,i}g_u(0|X_{i,u}))}{nh_e} \sum_{i=1}^{n} \xi_i + O_P \left( (n^{1+2\epsilon_0}h_1)^{-\frac{1}{2}} \right).
\]

Substituting (A.8) into the right hand side of the above relationship, we denote the derived three terms by \( I_1 \), \( I_2 \) and \( I_3 \), respectively. Note that
\[
\sqrt{nh_e} I_1 = O_P \left( \sqrt{nh_e} h_1^2 \right) = O_P \left( n^{-\frac{3\epsilon_0}{2}} \right).
\] (A.11)

\( I_2 \) is of the same order as that of
\[
\frac{1}{n^2} \sum_{i=1}^{n} \sum_{1 \leq j \neq i \leq n} \eta_{i,j} = \frac{1}{n^2} \sum_{i=1}^{n} \sum_{1 \leq j \neq i \leq n} \left( \eta_{i,j} - \mathbb{E}_i \eta_{i,j} \right) + \frac{n - 1}{n^2} \sum_{i=1}^{n} \mathbb{E}_i \eta_{i,j} = I_{21} + I_{22}.
\]

Since \( I_{21} \) is a degenerated U-statistic, it follows that \( \sqrt{nh_e} I_{21} = o_P(1) \) (see S.9 in the online supplement). By the standard WLLN, it can be obtained that \( \sqrt{nh_e} I_{22} = O_P \left( \sqrt{h_1} \right) \). Therefore,
we have \( \sqrt{n}h_eI_2 = o_P(1) \). Analogously, it can also be obtained that \( \sqrt{n}h_eI_3 = o_P(1) \). From these two relationships and (A.11), we have that

\[
\sqrt{n}h_e(\hat{\beta}_3 - \beta_{3_{oracle}}) = o_P(1).
\]  
(A.12)

Finally, combining (A.12) and (A.10), the theorem holds. \( \Box \)

References

Figure 1: Panel (a) and panel (b) plot the median function with respect to distance from the non-parametric (our approach) and semi-parametric approaches, respectively. Panel (c) and panel (d) give the median function with respect to time-of-day from the non-parametric and semi-parametric approaches, respectively. For better resolution, we truncate those distances that exceed 10 kms. There are very few calls that entail distances larger than 10 kms.
Figure 2: Panel (a) and panel (b) give the quantile function estimates for $\alpha=0.25$ and for distance and time-of-day, respectively. Panel (c) and panel (d) plot the quantile function estimates for $\alpha=0.75$ and for distance and time-of-day, respectively. In all panels, solid lines correspond to non-parametric estimates (our approach) while dashed lines correspond to semi-parametric estimates.
Supplementary material for

“Efficient Estimation of an Additive Quantile Regression Model”

by Yebin Cheng, Jan G. De Gooijer and Dawit Zerom

In this supplementary note we provide proofs for the results (A.2) - (A.5) of Theorem 2.1, Proposition 2.2 and Proposition 3.1. The note also includes intermediate lemmas that are used in the derivations of the theorems and propositions.

The following additional references are used in this supporting note.

Proofs of the relationships (A.2) to (A.5)

1). Proof of (A.2).

By variable substitution, Taylor expansion and i) of C4, it can be inferred that

\[ \mathbb{E} \xi_i^2 = h_1^2 \int \left( \frac{K(t_u)}{h_1} \right)^2 \frac{Q_2(x_u + h_1 t_u, w_u)f_2^2(w_u)}{f(x_u + h_1 t_u, w_u)} dt_u dw_u (1 + o(1)) = \sigma_2^2 (1 + o(1)) \]  

(S.1)

where \( \sigma_2^2 \) is as defined in Theorem 2.1. Using C6 and variable substitution, it follows that cov(\( \xi_1, \xi_{i+1} \)) = \( O(h_1) \). Let \( m_n \) be a sufficiently large integer with the restriction \( m_n h_1 \to 0 \). For \( \delta > 2 \) introduced in C4, by Davydov (1968) inequality, C4 and the fact that \( (\mathbb{E} |\xi_1|^\delta)^{\frac{2}{\delta}} = O \left( h_1^{\frac{2}{\delta}-1} \right) \), we obtain

\[ \sum_{i=m_n}^{n} (n-i) |\text{cov}(\xi_1, \xi_{i+1})| \leq Cn \sum_{i=m_n}^{n} \pi_i^{1-\frac{2}{\delta}} (\mathbb{E} |\xi_1|^\delta)^{\frac{2}{\delta}} = o(1). \]

Therefore,

\[ \mathbb{I}D \left( \sum_{i=1}^{n} \frac{\xi_i}{\sqrt{n}} \right) = \mathbb{E} \xi_i^2 + \sum_{i=1}^{m_n} + \sum_{i=m_n+1}^{n} \frac{2(n-i)}{n} \text{cov}(\xi_1, \xi_{i+1}) = \sigma_2^2 (1 + o(1)) \]  

(S.2)
where the operator $\mathcal{D}$ is as defined in Lemma 2. Then, in view of (S.2), C4, C5, and following the proofs of (32)-(35) in Cai and Ould-Saïd (2003), we conclude that (A.2) holds.

2). Proof of (A.3).

We first write it as $S_{2,n} = I_1 - I_2 + I_3 + I_4 + I_5$, where

$$I_1 = \frac{1}{nh_1} \sum_{i=1}^{n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) \left( \hat{f}_w(W_{i,u}) - E_i \hat{f}_w(W_{i,u}) \right) \left( \frac{1}{f(X_i)} - \frac{1}{f(X_i)} \right) Q_{\alpha}(X_i),$$

$$I_2 = \frac{1}{nh_1} \sum_{i=1}^{n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) \left( \hat{f}_w(X_i) - f(X_i) \right)^2 Q_{\alpha}(X_i) E_i \hat{f}_w(W_{i,u}),$$

$$I_3 = \frac{1}{nh_1} \sum_{i=1}^{n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) \left( \hat{f}_w(X_i) - f(X_i) \right)^2 Q_{\alpha}(X_i) E_i \hat{f}_w(W_{i,u}),$$

$$I_4 = \frac{1}{nh_1} \sum_{i=1}^{n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) Q_{\alpha}(X_i) f(X_i) \left( \hat{f}_w(W_{i,u}) - E_i \hat{f}_w(W_{i,u}) \right),$$

$$I_5 = \frac{1}{nh_1} \sum_{i=1}^{n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) Q_{\alpha}(X_i) f(X_i) \left( E_i \hat{f}_w(W_{i,u}) - f_w(W_{i,u}) \right)$$

and the operator $E_i$ is as defined in Lemma 4. By C1 and the dominated convergence theorem, it can be inferred that $f_w(w_u)$ has partial derivatives up to order $\bar{p}$. Thus, it holds that

$$E_i \hat{f}_w(W_{i,u}) - f_w(W_{i,u}) = \frac{1}{h_2^{d-1}} E_i L_1 \left( \frac{W_{i,u} - W_{j,u}}{h_2} \right) - f_w(W_{i,u}) = O \left( h_2^{\bar{p}} \right).$$

From this, WLLN and $\bar{p} > \frac{pd}{p+1}$, we know that $I_5 = O_{\mathbb{P}} \left( h_2^{\bar{p}} \right) = o_{\mathbb{P}} \left( (nh_1)^{-\frac{1}{2}} \right)$. By virtue of the uniform weak law of large number, it can be inferred that

$$\hat{f}_w(W_{i,u}) - E_i \hat{f}_w(W_{i,u}) = O_{\mathbb{P}} \left( (nh_2^{d-1})^{-\frac{1}{2}} \right). \tag{S.3}$$

Let

$$\xi_{ij} = K \left( \frac{x_u - X_{i,u}}{h_1} \right) \left( L_1 \left( \frac{W_{i,u} - W_{j,u}}{h_2} \right) - E_i L_1 \left( \frac{W_{i,u} - W_{j,u}}{h_2} \right) \right) Q_{\alpha}(X_i),$$

$$J_1 = \frac{1}{n^2 h_1 h_2^{d-1}} \sum_{i=1}^{n} \sum_{1 \leq j \neq i \leq n} \left( \xi_{ij} - E_j \xi_{ij} \right) \quad \text{and} \quad J_2 = \frac{2(n-1)}{n^2 h_1 h_2^{d-1}} \sum_{j=1}^{n} E_j \xi_{ij}.$$

Thus, $I_4 = J_1 + J_2$. Noting that $E_i \xi_{ij} = 0$, $J_1$ is a degenerated U-statistic. By C4 and C6, it can be inferred that $\sup_{i \neq j} E_j |\xi_{ij}| = O \left( h_1 h_2^{d-1} \right)$. Hence, applying Lemma 3 and vi) of C5, we obtain $J_1 = o_{\mathbb{P}} \left( (nh_1)^{-\frac{1}{2}} \right)$. To deal with $J_2$, let $\xi_j = E_j \left( K \left( \frac{x_u - X_{i,u}}{h_1} \right) L_1 \left( \frac{W_{i,u} - W_{j,u}}{h_2} \right) Q_{\alpha}(X_i) \right)$.
As in (S.2) and taking $m_n h_1 = o(1)$, it follows that $\mathbb{E}(\varepsilon_1^2) = O\left(\left(h_1 h_2^{d-1}\right)^2\right)$, 

$$
\sum_{j=1}^{m_n} (n-j) \text{cov}(\varepsilon_1, \varepsilon_{j+1}) = O\left(n m_n \left(h_1 h_2^{d-1}\right)^2\right),
$$

and

$$
\sum_{j=m_n+1}^{n} (n-j) \text{cov}(\varepsilon_1, \varepsilon_{j+1}) \leq C n \sum_{j=m_n+1}^{n} \beta_j^{1-\frac{2}{p}} \left(h_1 h_2^{d-1}\right)^{\delta} \hat{\beta}^j = C n \sum_{j=m_n+1}^{n} \beta_j^{1-\frac{2}{p}} \left(h_1 h_2^{d-1}\right)^2.
$$

From the above three equations, we see that $\mathbb{E}(J_2) = o\left(\frac{1}{nk_1}\right)$. Thus, $J_2 = o_p\left((nh_1)^{-\frac{1}{2}}\right)$ and so does for $I_4$. Moving to $I_2$, note that

$$
\mathbb{E}_i \hat{f}(X_i) - f(X_i) = O\left(n^{-\bar{p}/(d+\bar{p})}\right) = o\left((nh_1)^{-\frac{1}{2}}\right), \quad (S.4)
$$

where the last equation follows from $\bar{p} > \frac{pd}{p+1}$ and $h_1 \leq C n^{-\frac{1}{p+1}}$. Similar to the proof of $I_4$, it can be obtained that

$$
\frac{1}{nh_1} \sum_{i=1}^{n} K \left(\frac{x_i - X_{i,u}}{h_1}\right) \frac{\hat{f}(X_i) - \mathbb{E}_i \hat{f}(X_i)}{f^2(X_i)} Q_\alpha(X_i) \mathbb{E}_i \hat{f}_w(W_{i,u}) = o_p\left((nh_1)^{-\frac{1}{2}}\right). \quad (S.5)
$$

Therefore, from (S.4), (S.5) and WLLN, it can be obtained that $I_2 = o_p\left((nh_1)^{-\frac{1}{2}}\right)$. To deal with $I_3$, it is easy to see that

$$
|\hat{f}(X_i) - f(X_i)| \leq |\hat{f}(X_i) - \mathbb{E}_i \hat{f}(X_i)| + |\mathbb{E}_i \hat{f}(X_i) - f(X_i)| = O_p\left(n^{-\frac{p}{p+1}}\right), \quad (S.6)
$$

where we use WLLN and (S.4). Further, the assumption $\bar{p} > \frac{pd}{p+1}$ and WLLN implies that $I_3 = o_p\left((nh_1)^{-\frac{1}{2}}\right)$. Finally, from (S.6), (S.3), WLLN and $\bar{p} > \frac{pd}{p+1}$, it can be inferred that

$$
I_1 = O_p\left(n^{-\frac{1}{2}} \left(1 - \frac{d-1}{p+1}\right) \cdot n^{-\frac{p}{p+1}}\right) = o_p\left((nh_1)^{-\frac{1}{2}}\right).
$$

3). Proof of (A.4) and (A.5).

By the same method as that of $S_{2,n}$, it can be proved that $S_{1,n}' = o_p\left((nh_1)^{-\frac{1}{2}}\right)$, where $S_{1,n}' = S_{1,n} - S_{1,n}''$ and

$$
S_{1,n}'' = \frac{1}{nh_1} \sum_{i=1}^{n} K \left(\frac{x_i - X_{i,u}}{h_1}\right) \frac{f_w(W_{i,u})}{f(X_i)} \left(\hat{Q}_\alpha(X_i) - Q_\alpha(X_i)\right). \quad (S.7)
$$

Inserting (S.14) into (S.7), we obtain two terms (denoted by $S_{4,n}$ and $S_{5,n}$) where the second (which is $S_{5,n}$) is the remainder term that is of order $o_p\left((nh_1)^{-\frac{1}{2}}\right)$ because $\kappa < \frac{2p+3-(2p+1)\left(1-\frac{2\varepsilon}{3\delta}\right)}{3d(2p+1)(1+\frac{2\varepsilon}{3\delta})}$. 

25
Let \( \varphi_{ij} = e^T B_{i,n}^{-1} K_{ji} V_{ji} ( \| Y_j \leq V_{ji} \beta X_j \| - \| \mathcal{E}_{\alpha,j} \| \leq 0 ) \). By SLLN, \( \kappa > \frac{1}{2\beta + 1} \) and Taylor expansion for \( Q(x, y) \), it could be proved that

\[
\frac{1}{nh^d} \sum_{1 \leq j \neq i \leq n} \varphi_{ij} = O \left( h^p \right) = o \left( \frac{1}{\sqrt{nh_1}} \right) \tag{S.8}
\]

holds almost surely and uniformly for \( i = 1, \ldots, n \). Thus, by WLLN, we obtain that

\[
\frac{1}{n^2 h_1 h^d} \sum_{i=1}^{n} \sum_{1 \leq j \neq i \leq n} K \left( \frac{x_u - X_{i,u}}{h_1} \right) f_w \left( W_{i,u} \right) f(X_i) \varphi_{ij} = o_p \left( \frac{1}{\sqrt{nh_1}} \right).
\]

Therefore,

\[
S_{4,n} = \frac{1}{n^2 h_1 h^d} \sum_{i=1}^{n} \sum_{1 \leq j \neq i \leq n} \eta_{ij} + o_P \left( \frac{1}{\sqrt{nh_1}} \right).
\]

Note that \( \mathbb{E}_j \eta_{ij} = 0 \). According to \( H \)-decomposition of U-statistic,

\[
S_{4,n} = \frac{1}{n^2 h_1 h^d} \sum_{i=1}^{n} \sum_{1 \leq j \neq i \leq n} (\eta_{ij} - \mathbb{E}_j \eta_{ij}) + \frac{n-1}{n^2 h_1 h^d} \sum_{j=1}^{n} \mathbb{E}_j \eta_{ij} + o_P \left( \frac{1}{\sqrt{nh_1}} \right).
\]

Denote the first two terms of \( S_{4,n} \) by \( S'_{4,n} \) and \( S''_{4,n} \), respectively. Trivially, \( S'_{4,n} \) is a degenerated U-statistic. Therefore, by applying iv) of C5 and Lemma 3 and taking \( \frac{1}{s} = 1 - \frac{k+1}{\theta} - \epsilon \) and \( k = 2 \), we know that

\[
(nh_1)^{\frac{1}{2}} \mathbb{E} \left| S'_{4,n} \right|^k \leq \left( \frac{nh_1}{(n^2 h_1 h^d)^k} \right) \left( 1 + \sum_{i=1}^{n} \beta_i^{1-k} \right) \sup_{1 \leq i \neq j \leq n} \left( \mathbb{E} \left| \eta_{ij} \right|^s \right)^{\frac{1}{s}} \leq O \left( \left( nh_1 \left( h_1 h^d \right)^{\frac{2}{3} + \epsilon} \right)^{-1} \right) = o(1) \tag{S.9}
\]

Hereby, from this and Markov inequality, it can be inferred that \( S'_{4,n} = o_P \left( \left( nh_1 \right)^{-\frac{1}{2}} \right) \). By variable substitution and \( h/h_1 \to 0 \), it can be inferred that

\[
\mathbb{E} \left( \phi_1^2 \right) = \alpha (1 - \alpha) \mathbb{E} \left( \int K \left( \frac{x_u - X_{i,u}}{h_1} \right) f_w \left( W_{i,u} \right) f(X_i) e_1^T B_{i,n}^{-1} L_j V_{ji} \right)^2
\]

\[
\sim \alpha (1 - \alpha) h^{2d} \mathbb{E} \left( \int K \left( \frac{x_u - h s_u - X_{j,u}}{h_1} \right) g(0, X_j + h s) f(X_j + h s) f_w \left( W_{j,u} + h s - u \right) ds \right)^2
\]

\[
\sim Ch_1 h^{2d} \sigma_1^2 \tag{S.10}
\]

where \( B_2 = \int V_1(s) V_1^T(s) L(s) ds \), and the fact \( e_1^T B_2^{-1} \int V_1(s) L(s) ds = 1 \), which follows from properties of the inverse matrix and the adjoint matrix, is used in the last step. Taking \( m_n h_1 = o(1) \) and using the same arguments used earlier, we can obtain that

\[
\sum_{j=1}^{m_n} (n-j) |\text{cov}(\phi_1, \phi_{j+1})| = O \left( n m_n h^{2d} h_1^2 \right).
\]
Further, according to Davydov’s inequality, $\delta > 2$ in C4 and iv) of C5, it can be shown that

\[ \sum_{j=m_n+1}^{n} (n-j)[\text{cov}(\phi_1, \phi_{j+1})] \leq Cn \sum_{j=m_n+1}^{n} \frac{1-2^j}{n} \left( h^d h_1 \right)^2 = Cnm_n^{1-\theta (1-\frac{2}{\theta})} h^2 d h_1^2. \]

Thus using (S.10) and the above two equations, we see that $D(S_{4,n}^1) = \frac{\delta^2}{n^{\frac{\theta}{\theta-1}}}$. Further, following the same line of proofs as (A.2), it can be obtained that (A.4) holds.

\[ \square \]

**Proof of Proposition 2.2**

Note that $\hat{c}_\alpha = \frac{1}{n} \sum_{i=1}^{n} \hat{Q}_\alpha(X_i)$. Let

\[ \hat{c}_1 = \frac{1}{n} \sum_{i=1}^{n} (\hat{Q}_\alpha(X_i) - Q_\alpha(X_i)) \quad \text{and} \quad \hat{c}_2 = \frac{1}{n} \sum_{i=1}^{n} (Q_\alpha(X_i) - \mathbb{E}Q_\alpha(X_i)). \]

Thus, $\hat{c}_\alpha - c_\alpha = \hat{c}_1 + \hat{c}_2$. Similar to the proof of (S.8), it can be obtained that

\[ \hat{c}_1 = \frac{1}{n^2 h^d} \sum_{i=1}^{n} \sum_{1 \leq j \neq i \leq n} \hat{c}_1 B_{i,n}^{-1} L_{ji} V_{ji} [\alpha - \mathbb{I} (E_{\alpha,i} \leq 0)] + O_P \left( h^p + \left( n^{-d}\frac{1}{\eta h^d} \left( 1 + \frac{2}{\theta} \frac{1}{\eta h^d} \right) \right)^{-\frac{1}{2}} \right). \]

Using iii) of C5, the remainder term is of order $o_P \left( n^{-d}\frac{1}{\eta h^d} \right)$. Denote the first term of the above equation for $\hat{c}_1$ by $\hat{c}'_1$. Let $\eta_{i,j} = e_1^T B_{i,n}^{-1} L_{ji} V_{ji} [\alpha - \mathbb{I} (E_{\alpha,i} \leq 0)]$. Since $E_{\gamma} \eta_{i,j} = 0$, by $H$-decomposition of U-statistic, we have

\[ \hat{c}'_1 = \frac{1}{n^2 h^d} \sum_{i=1}^{n} \sum_{1 < j \neq i \leq n} (\eta_{i,j} - \mathbb{E}\eta_{i,j}) + \frac{n-1}{n^2 h^d} \sum_{i=1}^{n} \mathbb{E}\eta_{i,j} = A_1 + A_2. \]

Since $A_1$ is a degenerated U-statistic, by Lemma 3, iv) of C5, and taking $\frac{1}{\theta} = 1 - \frac{k+1}{\theta} - \varepsilon$ and $k = 2$, we have

\[ (nh_1)^{k/2} \mathbb{E}|A_1|^k \leq C(nh_1)^{k/2} \frac{n^k (\text{sup}_{i \neq j} |\mathbb{E}|\eta_{i,j}|^{1/s})^{1/s}}{(n^2 h^d)^k} \leq C(nh_1)^{k/2} \frac{n^k h^d/s}{(n^2 h^d)^k} \leq \frac{C h_1}{n h^d + \frac{s}{\theta} + \varepsilon} \to 0. \]

Thus, it follows that $A_1 = o_P \left( \frac{1}{\sqrt{n h_1}} \right)$. By WLLN, it can be derived that $A_2 = O_P \left( \frac{1}{\sqrt{n h_1}} \right)$. Further $\hat{c}_2 = o_P \left( \frac{1}{\sqrt{n h_1}} \right)$. Therefore, Proposition 2.2 holds.

\[ \square \]

**Proof of Proposition 3.1**

For $a \in \mathbb{R}^p$, denote by $\Delta_n(a, t_n) = \Delta_{n,1}(a, t_n) - \Delta_{n,1}(0)$, $\Delta_{n,1}(a, t_n) = \sum_{i=1}^{n} \Delta_{i,1}(a, t_{i,n})$, $\Delta_{i,2}(a, t_{i,n}) = \Delta_{i,1}(a, t_{i,n}) - \Delta_{i,1}(a, 0)$, $\Delta_{i,1}(a, t_{i,n}) = \sum_{i} K_{n,i} V_{a,i} [\alpha - \mathbb{I} (E_{\alpha,i} \leq a^T V_{a,i} + t_{i,n} - q_{\alpha,a}(X_{a,i}))].$
Let \( G(y|x_u) \) be the conditional distribution function of \( E_{\alpha,i} \) given that \( X_{i,u} = x_u \). Then, by Taylor expansion and condition C8, it can be inferred that

\[
\frac{IE\Delta_n(a,t_n)}{nh_e} = \sum_{i=1}^{n} \frac{IEK_{u,i}V_{u,i}}{nh_e} [G(a^TV_{u,i} + t_{i,u} - q_{\alpha,u}(X_{i,u})|X_{i,u}) - G(\beta^T_{u}V_{u,i} - q_{\alpha,u}(X_{i,u})|X_{i,u})]
\]

\[
= B_n (a - \beta_u) + \frac{IE(K_{u,i}g_u(0|X_{i,u}))}{nh_e} \sum_{i=1}^{n} t_{i,n} + O \left( r^2_n \right). \tag{S.11}
\]

From the definition of \( \hat{\beta}_{x_u} \), we know that \( \Delta_{n,1}(\hat{\beta}_{t_n}, t_n) = O(1) \). From this, (S.11), Lemma 12 and the following relationship

\[
- \Delta_{n,1}(\beta_{x_u}, 0) = [\Delta_{n}(a, t_n) - IE\Delta_n(a, t_n)] + E\Delta_n(a, t_n) - \Delta_{n,1}(a, t_n),
\]

it can be inferred that

\[
\hat{\beta}_{t_n} - \beta_{x_u} = -B_n^{-1} IE(K_{u,i}g_u(0|X_{i,u})) V_{u,i} \sum_{i=1}^{n} t_{i,n}
\]

\[
- \frac{B_n^{-1}}{nh_e} \sum_{i=1}^{n} K_{u,i}V_{u,i} \left[ \alpha - \mathbb{I}(Y_i - c_\alpha - Q_{\alpha,-u}(W_{i,u}) - \beta^T_{x_u}V_{u,i} \leq 0) \right] + O \left( \frac{n^{-\delta_0}}{\sqrt{nh_e}} \right). \tag{S.12}
\]

In the relationship above, if we set \( t_n = 0 \), then we can derive that

\[
\hat{\beta}_{oracle} - \beta_{x_u} = -B_n^{-1} \sum_{i=1}^{n} K_{u,i}V_{u,i} \left[ \alpha - \mathbb{I}(Y_i - c_\alpha - Q_{\alpha,-u}(W_{i,u}) - \beta^T_{x_u}V_{u,i} \leq 0) \right]
\]

\[
+ O \left( \frac{n^{-\delta_0}}{\sqrt{nh_e}} \right). \tag{S.13}
\]

In view of Equations (S.12) and (S.13), it can be inferred that Proposition 3.1 holds.

**Lemmas for Theorems 2.1 and Proposition 2.2**

Lemmas 1, 2 and 3 are on absolutely regular processes. For the proof of Lemma 1, we refer to Yoshihara (1978). The proofs of Lemmas 2, 3 and 4 are given by Cheng and De Gooijer (2008).

**Lemma 1.** Let \( F_1 \) and \( F_2 \) be the two distribution functions of the random vectors \( \xi_{i_1}, \ldots, \xi_{i_j} \) and \( \xi_{i_{j+1}}, \ldots, \xi_{i_k} \). \( h(x_1, \ldots, x_k) \) is a Borel measurable function with the bound \( M > 0 \). Then

\[
\left| IEh(\xi_{i_1}, \ldots, \xi_{i_k}) - \int \cdots \int h(x_{i_1}, \ldots, x_{i_j}, x_{i_{j+1}}, \ldots, x_{i_k}) \, dF^{(1)}(x_{i_1}, \ldots, x_{i_j}) \right| \leq 2M \pi (i_{j+1} - i_j).
\]

28
Lemma 3. Let $U_n = \sum_{1 \leq i < j \leq n} h_n(\xi_i, \xi_j)$ be a degenerated U-statistic with the symmetric kernel $h_n(\cdot, \cdot)$, i.e., for any $t \in \mathbb{R}$, $\mathbb{E}h_n(\xi, \cdot) = 0$. Then for $k \in \mathbb{N}$, there exists a universal constant $C > 0$ such that

$$\mathbb{E}U_n^k \leq Cn^k \left(1 + \sum_{i=1}^{n-1} i^k \beta_i^{1-\frac{s}{2}}\right) M_{sk}^k,$$

where $s > 1$ and

$$M_{sk} = \sup_{(i_1,i_2)} \mathbb{P}\left(\int |h_n(\xi_{i_1}, \xi_{i_2})|^s d\mathbb{P}\right)^\frac{1}{s},$$

with $\mathbb{P}$ being either the probability measure $\mathbb{P}_{\xi_{i_1}}$ or $\mathbb{P}_{\xi_{i_1}} \otimes \mathbb{P}_{\xi_{i_2}}$.

Lemma 4. Define an operator $\mathbb{E}_i$ as $\mathbb{E}_i g(\xi_j, \xi_i) = g_2(\xi_i)$ for any $i \neq j$. Then, under the conditions C1 to C6, the following Bahadur representation for conditional quantiles holds almost surely and uniformly for $1 \leq i \leq n$ that

$$Q_{\alpha}(X_i) - Q_{\alpha}(X_i) = \frac{e_i^T B_{i,n}^{-1}}{nh^d} \sum_{1 \leq j \neq i \leq n} L_{ij} V_{ji} \left(\alpha - \mathbb{I} (Y_j \leq V_{ij}^T \beta X_i)\right) + O \left(n^{-1 - \frac{2q}{2q+1}} + \frac{2q}{2q+1} \left(1 + \frac{2q}{2q+1}\right)^\frac{1}{q}\right),$$

where $L_{ji} = L \left(\frac{X_i - X_j}{h}\right)$, $V_{ji} = V_1 \left(\frac{X_i - X_j}{h}\right)$ and $B_{i,n} = \frac{1}{n^q} \mathbb{E}_i \left(L_{ji} V_{ji} V_{ji}^T g(0|X_j)\right)$.

**Lemmas for Proposition 3.1**

We show a sequence of lemmas with proofs that help to show the result in Proposition 3.1. Without loss of generality, in the proofs of Lemma 5 to Lemma 12, $\alpha$ is taken to be $\frac{1}{2}$, condensing presentation of the proofs.

For $a \in \mathbb{R}^p$, denote by $\Lambda(a, t_n) = \frac{1}{m_n c} \sum_{i=1}^{n} \Lambda_i$ and

$$\Lambda_i = \Lambda_i(a, t_i, n) = K_{u,i} \left(|Y_i - c_\alpha - Q_{\alpha, -u} (W_{i,u}) - a^T V_{u,i} - t_{i,n}| \right.\left. - |Y_i - c_\alpha - Q_{\alpha, -u} (W_{i,u}) - \beta_{\alpha}^T V_{u,i}|\right).$$
Lemma 5. There exists a constant $M_1 > 0$ such that, with probability one,

$$|\Lambda(a, t_n) - \mathbb{E}\Lambda(a, t_n)| \leq \frac{M_1 r_n}{\sqrt{\log n}} \quad (S.15)$$

holds uniformly for $|a - \beta_{x_n}| = Cr_n^\frac{1}{2}$ and $|t_{i,n}| \leq Cr_n$, $i = 1, 2, \ldots, n$.

Proof. Divide the interval $|t| \leq Cr_n$ into a sequence of subintervals with equidistance $l_n = r_n/\sqrt{\log n}$. Let $\{v_{i,n}\}$ be the set of all the grid points of the number $N_1 = O(\sqrt{\log n})$. For any $|s_{i,n}| \leq Cr_n$, $i = 1, 2, \ldots, n$, let $t_{i,n}$ be the left absissa of the corresponding subinterval. Denote by $s_n = (s_{1,n}, \ldots, s_{n,n})$ and $t_n = (t_{1,n}, \ldots, t_{n,n})$. Next, we divide the sphere $|a - \beta_{x_n}| = Cr_n^\frac{1}{2}$ into a sequence of smaller areas with the length of the sides $l_n$. The number of such kinds of smaller areas is of order $N_2 = (r_n^{-1} \log n)^{\frac{p-1}{2}}$. For any $b$ in the mentioned sphere, let $a$ be the nearest grid point to $b$. Then, we have that

$$|\Lambda(b, s_n) - \Lambda(a, t_n) - \mathbb{E}[\Lambda(b, s_n) - \Lambda(a, t_n)]| \leq \frac{t_n}{nh_e} \sum_{i=1}^{n} (K_{u,i} + \mathbb{E}K_{u,i}). \quad (S.16)$$

Below, we will use the fact that $\mathbb{E}|\Lambda_i(a, t_{j,n})|^s \leq Ch_{e_1} r_n^\frac{s}{2}$ for any $s > 0$. By using Theorem 3 of Yoshihara (1978), Corollary 2.1 of Hall and Heyde (1980) and Rosenthal inequality, and taking $m = (nh_e)^{\frac{1}{2}}$ and for a constant $r$ which sufficiently large, we can see that

$$N_2 \mathbb{P}\left\{ \bigcup_{t_n} \left\{ |\Lambda(a, t_n) - \mathbb{E}\Lambda(a, t_n)| \geq \frac{M_1 r_n}{\sqrt{\log n}} \right\} \right\}$$

$$\leq N_2 \sum_{j=1}^{N_1} \mathbb{P}\left\{ \max_{1 \leq k \leq n} \left| \sum_{i=1}^{k} (\Lambda_i(a, v_{j,n}) - \mathbb{E}\Lambda_i(a, v_{j,n})) \right| \geq \frac{nh_2 r_n}{N_1 \sqrt{\log n}} \right\}$$

$$\leq N_2 \sum_{j=1}^{C \log n} \left\{ C(r) \sum_{l=1}^{m} \frac{n\mathbb{E}|\Lambda_i(a, v_{j,n})|^r + \left[ \sum_{i=1}^{n} \mathbb{E}(\Lambda_i^2(a, v_{j,n})) \right]^\frac{1}{2}}{(m^{-1} r_n)^{\frac{r}{2}}} + n\pi(m) \right\}$$

$$\leq C N_1 N_2 \left\{ m^{r+1} \left( \frac{(\log n)^2}{nh_e r_n} \right)^{\frac{1}{2}} + n\pi(m) \right\} \leq \frac{C}{n (\log n)^{\frac{r}{2}}}, \quad (S.17)$$

where $C(r)$ is a constant related only to $r$. The condition C4 on $\theta$ is used in the last inequality.

Let $L_1 = \sum_{i=1}^{n} K_{u,i}$. Using Lemma 1 and taking $\theta \geq p + 9$ and $m_n = O(h_2^{-1})$, it can be inferred that

$$\mathcal{D}(L_1) \leq u \mathbb{E}K_{u_1}^2 + \sum_{i=1}^{u-1} \text{cov}(K_{u,1}, K_{u,i+1}) \leq uh_e + u \sum_{i=1}^{m_n} \text{cov}(K_{u,1}, K_{u,i+1}) + Cu \sum_{i=m_n}^{\infty} \pi_i \leq Cuh_e + um_n h_e^2 + Cm_n^{(\theta-1)} \leq Cuh_e. \quad (S.18)$$
For suitable large constant $M_1$, we have that $\frac{l_n}{nh_e} n \mathbb{E} K_{u,i} \leq M_1 r_n / \sqrt{\log n}$. Thus, by letting $u = \frac{nh_e}{\log n}$, it can be obtained subsequently that

$$N_2 P \left\{ \sum_{i=1}^{n} (K_{u,i} + \mathbb{E} K_{u,i}) \geq M_1 r_n / \sqrt{\log n} \right\}$$

$$\leq N_2 P \left\{ \sum_{i=1}^{n} (K_{u,i} - \mathbb{E} K_{u,i}) \geq CM_1 nh_e \right\}$$

$$\leq N_2 \left\{ \exp \left[ \frac{(CM_1 nh_e)^2}{2u \mathbb{I}D(L_1) + 2u CM_1 nh_e} \right] + \frac{n}{u} \pi(u) \right\} \leq \frac{C}{n (\log n)^{2}} \tag{S.19}$$

By virtue of Borel-Cantelli Lemma, (S.17) and (S.19), it follows that (S.15) holds. \hfill \Box

**Lemma 6.** It holds uniformly for $|t_{i,n}| \leq C r_n$, $i = 1, 2, \ldots, n$, with probability one that $\| \hat{\beta}_{t_n} - \beta_{x_u} \| \leq M_1 r_n^{\frac{3}{2}}$.

The proof of the lemma above is similar to Lemma 3.2 of Honda (2000).

Denote by

$$\xi_{n,i}(a, t_{i,n}) = -K_{u,i} V_{u,i} \left[ 2 \mathbb{I} \left( Y_i - c_{\alpha} - Q_{\alpha, u}(W_{i,u}) - a^T V_{u,i} - t_{i,n} \geq 0 \right) - 1 \right].$$

**Lemma 7.** There exists a constant $M_2 > 0$ such that, with probability one,

$$\left| \sum_{i=1}^{n} \xi_{n,i}(a, t_{i,n}) - 2n h_e g_u(0|x_u)f_u(x_u) \int K_{u}(s)V(s)V^T(s)ds(a - \beta_{x_u}) \right| \leq M_2 \sqrt{n^{1+\epsilon}h_e}$$

holds uniformly for $\|a - \beta_{x_u}\| \leq M_1 r_n^{\frac{1}{2}}$ and $|t_{i,n}| \leq C r_n$ with $1 \leq i \leq n$.

**Proof.** First note that, when $|x_{i,u} - x_u| \leq h_e$, it holds that

$$-q_{\alpha,u}(x_{i,u}) + a^T V_{u,i} = -(q_{\alpha,u}(x_{i,u}) - \beta_{x_u}^T V_{u,i}) + (a - \beta_{x_u})^T V_{u,i} = O(h_e^p) + (a - \beta_{x_u})^T V_{u,i}.$$

Thus, by using variable substitution, the mean value of the integration and Taylor expansion, we can obtain

$$\sum_{i=1}^{n} \mathbb{E} \xi_{n,i}(a, 0) = 2 \sum_{i=1}^{n} \int K_{u,i} V_{u,i} \int_{0}^{-q_{\alpha,u}(x_{i,u}) + a^T V_{u,i}} g_u(s|x_{i,u}) ds f_u(x_{i,u}) dx_{i,u}$$

$$= 2n h_e g_u(0|x_u)f_u(x_u) \int K_{u}(s)V(s)V^T(s)ds(a - \beta_{x_u}) + O(n h_e |a - \beta_{x_u}|^2 + n h_e^{p+1}).$$

Divide the ball $\|a - \beta_{x_u}\| \leq M_1 r_n^{\frac{1}{2}}$ into a sequence of smaller cubics with the length of the side $l_n = r_n$. Thus, the total number of different smaller cubics is of order $r_n^{-\frac{p}{2}}$. Denote by
\[ \eta_i = K_{n,i} \mathbb{I} \left( |Y_i - c_\alpha - Q_{\alpha,-u}(W_{i,u}) - a^TV_{u,i}| \leq Cr_n \right). \]
For any \( b \) in the mentioned ball, \( a \) is the corresponding nearest grid point. Clearly, we have that
\[
\left| \sum_{i=1}^{n} (\xi_{n,i}(b, t_{i,n}) - \mathbb{E}\xi_{n,i}(b, t_{i,n})) - \sum_{i=1}^{n} (\xi_{n,i}(a, 0) - \mathbb{E}\xi_{n,i}(a, 0)) \right| \leq 2 \sum_{i=1}^{n} (\eta_i + \mathbb{E}\eta_i).
\]

It can be calculated that \( n\mathbb{E}\eta_i \leq C \sqrt{n^{1+\varepsilon_0}h_e} \). Thus, by the same method as that of (S.19) and taking \( u = \sqrt{n^{1+\varepsilon_0}h_e}/\log n \) and \( m_n = h_e r_n^2 \), we obtain that
\[
r_n^{-p} \mathbb{P} \left\{ \sum_{i=1}^{n} \eta_i \geq M_2 \sqrt{n^{1+\varepsilon_0}h_e} \right\} \leq \frac{1}{n(\log n)^2}.
\]

Analogously, by letting \( u = \sqrt{n^{1+\varepsilon_0}h_e}/\log n \) and \( m_n = Ch_e \), it holds that
\[
r_n^{-p} \mathbb{P} \left\{ \left| \sum_{i=1}^{n} (\xi_{n,i}(a, 0) - \mathbb{E}\xi_{n,i}(a, 0)) \right| \geq M_2 \sqrt{n^{1+\varepsilon_0}h_e} \right\} \leq \frac{1}{n(\log n)^2}.
\]
Then, by Borel-Cantelli Lemma, Lemma 7 holds.

We now divide the ball \( \|a - \beta_{x_u}\| \leq M_1 r_n^{\frac{1}{2}} \) into a sequence of smaller cubics with the length of the sides \((n^{1-\varepsilon_0}h_e)^{-1}\). Denote \( B_n \) by the set of all the grid points, the number of which is of order \((n^{1-\varepsilon_0}h_e)^{\frac{1}{2}}\). Let \( \beta^*_{x_u} \) be nearest grid point to the point \( \hat{\beta}_{t_n} \). Then, we can see that \( \|\beta^*_{x_u} - \hat{\beta}_{t_n}\| \leq (n^{1-\varepsilon_0}h_e)^{-1}\).

**Lemma 8.** There exists a constant \( M_3 > 0 \) such that, with probability one,
\[
\max_{a \in B_n} \sum_{i=1}^{n} K_{u,i} V_{a,i} \mathbb{I} \left( |Y_i - c_\alpha - Q_{\alpha,-u}(W_{i,u}) - a^TV_{u,i} - t_{i,n}| \leq Cr_n \right) \leq M_3 \sqrt{n^{1+\varepsilon_0}h_e}
\]
holds uniformly for \( |t_{i,n}| \leq C_1 r_n \), \( 1 \leq i \leq n \).

**Proof.** Let
\[
\zeta_i(a, t_{i,n}, C_1) = K_{a,i} V_{a,i} \mathbb{I} \left( |Y_i - c_\alpha - Q_{\alpha,-u}(W_{i,u}) - a^TV_{a,i} - t_{i,n}| \leq C_1 r_n \right) .
\]

Then, there exists a constant \( C_2 > 0 \) such that
\[
\left| \sum_{i=1}^{n} [\zeta_i(a, t_{i,n}, C_1) - \zeta_i(a, 0, C_1)] \right| \leq C_2.
\]

Analogous to the proofs of (S.19) and (S.18), through letting \( u = \frac{1}{\log n} \sqrt{n^{1+\varepsilon_0}h_e} \) and \( m_n = h_e^{-1} r_n^2 \), we know that
\[
(n^{1-\varepsilon_0}h_e)^{\frac{1}{2}} \mathbb{P} \left\{ \left| \sum_{i=1}^{n} \zeta_i(a, 0, C_2) \right| \geq M_3 \sqrt{n^{1+\varepsilon_0}h_e} \right\} \leq \frac{C}{n(\log n)^2}.
\]
Thus, applying Borel-Cantelli lemma leads to Lemma 8.
Lemma 9. There exists a constant $C > 0$ such that, with probability one,
\[
\left| \sum_{i=1}^{n} K_{u,i} V_{u,i} \left[ 2\mathbb{I} \left( Y_i - c_a - Q_{\alpha,-u}(W_{i,u}) - \beta_{t_n}^T V_{u,i} - t_{i,n} \geq 0 \right) - 1 \right] \right| \leq C
\]
holds uniformly for $|t_{i,n}| \leq C_1 r_n$, $1 \leq i \leq n$.

Proof. See, for example, Lemma 3.3 of Honda (2000).

Lemma 10. There exists a constant $M_4 > 0$ such that, with probability one,
\[
\left| \sum_{i=1}^{n} K_{u,i} V_{u,i} \left[ 2\mathbb{I} \left( Y_i - c_a - Q_{\alpha,-u}(W_{i,u}) - (\beta_{x_u}^*)^T V_{u,i} - t_{i,n} \geq 0 \right) - 1 \right] \right| \leq M_4 \sqrt{n^{1+\epsilon_0} h_e}
\]
holds uniformly for $|t_{i,n}| \leq C_1 r_n$, $1 \leq i \leq n$.

Proof. The left hand side of the relationship above is bounded by $I_1 + I_2$ with
\[
I_1 = 2 \left| \sum_{i=1}^{n} K_{u,i} V_{u,i} \left[ \mathbb{I} \left( Y_i - c_a - Q_{\alpha,-u}(W_{i,u}) - (\beta_{x_u}^*)^T V_{u,i} - t_{i,n} \geq 0 \right) \right. \right.
\]
\[
- \left. \left. \mathbb{I} \left( Y_i - c_a - Q_{\alpha,-u}(W_{i,u}) - \beta_{t_n}^T V_{u,i} - t_{i,n} \geq 0 \right) \right] \right| \left. \right| \left. \right|
\]
and
\[
I_2 = \left| \sum_{i=1}^{n} K_{u,i} V_{u,i} \left[ 2\mathbb{I} \left( Y_i - c_a - Q_{\alpha,-u}(W_{i,u}) - \beta_{t_n}^T V_{u,i} - t_{i,n} \geq 0 \right) - 1 \right] \right| .
\]

When $|Y_i - c_a - Q_{\alpha,-u}(W_{i,u}) - (\beta_{x_u}^*)^T V_{u,i} - t_{i,n}| \leq r_n$, by SLLN, it follows that
\[
I_1 \leq 2 \sum_{i=1}^{n} K_{u,i} V_{u,i} \mathbb{I} \left( |Y_i - c_a - Q_{\alpha,-u}(W_{i,u}) - (\beta_{x_u}^*)^T V_{u,i} - t_{i,n}| \leq r_n \right) \leq C \sqrt{n^{1+\epsilon_0} h_e}
\]
holds with probability one. For any two reals $a_1$ and $a_2$, define $U(a_1) = \frac{a_1}{|a_1|}$ for $a_1 \neq 0$ and $U(a_1) = 1$ if $a_1 = 0$. Note that $2\mathbb{I}(a_1 \geq 0) - 1 = U(a_1)$ and $|U(a_1) - U(a_2)| \leq \frac{2|a_1 - a_2|}{|a_1|}$. Then, if $|Y_i - c_a - Q_{\alpha,-u}(W_{i,u}) - (\beta_{x_u}^*)^T V_{u,i} - t_{i,n}| \geq r_n$, from the known result $|\beta_{x_u}^* - \beta_{t_n}| \leq (n^{1-\epsilon_0} h_e)^{-1}$ and SLLN, we get to know that, with probability one,
\[
I_1 \leq 2 \sum_{i=1}^{n} K_{u,i} \left| \beta_{x_u}^* - \beta_{t_n} \right| \leq C \sqrt{n^{1+\epsilon_0} h_e}.
\]

In view of Lemma 9, $I_2 \leq C$. Therefore, the lemma holds.

Lemma 11. It holds uniformly for $|t_{i,n}| \leq C r_n$, $i = 1, \ldots, n$, with probability one that $\left\| \hat{\beta}_{t_n} - \beta_{x_u} \right\| \leq C r_n$. 

33
**Proof.** For a satisfying that \( M_1 r_n^\frac{1}{2} \geq \|a - \beta_{x_n}\| > M_5 r_n \), it follows from Lemma 7 that

\[
\left| K_{u,i} V_{u,i} \left[ 2I (Y_i - c_\alpha - Q_{\alpha,-u} (X_{i,-u}) - a^T V_{u,i} - t_{i,n} \geq 0) - 1 \right] \right| \\
\geq -M_2 \sqrt{n^{1+\varepsilon_0} h_e} + \| 2n h_e g_u(0|x_u) f(x_u) \int K_e(s) V(s) V^T(s) ds (a - \beta_t) \| \\
\geq (CM_5 - M_2) \sqrt{n^{1+\varepsilon_0} h_e}.
\]

We could choose sufficiently large \( M_5 > 0 \) such that \( CM_5 - M_2 > M_4 \). Hence, by Lemma 10, we have that \( \| \beta_{x_n} - \beta_{x_n}\| \leq M_5 r_n \). Therefore, in view that \( \| \beta_{x_n} - \beta_{x_n}\| \leq (n^{1-\varepsilon_0} h_e)^{-1} \), it holds with probability one that \( \| \hat{\beta}_{t_n} - \beta_{x_n}\| \leq (M_5 + 1) r_n \).

**Lemma 12.** With probability one, it holds uniformly for \( \|a - \beta_{x_n}\| \leq Cr_n \) and \( |t_{i,n}| \leq Cr_n \), \( i = 1, 2, \ldots, n \), that

\[
\Delta_n(a, t_n) - \mathbb{E} \Delta_n(a, t_n) = O \left( (nh_e)^\frac{1}{2} n^{-\varepsilon_0} \right). \tag{S.20}
\]

**Proof.** Divide the ball \( \|a - \beta_u\| \leq Cr_n \) into a sequence of cubics with the length of the sides \( l_n = \frac{n^{\varepsilon_0}}{\sqrt{m_n}} \). As before, the total number of different cubics \( N_2 \) is of order \( n^{\frac{3}{2} + \varepsilon_0} \). For any \( b \) in the mentioned ball, let \( a \) be the center of the cubic in which \( b \) locates. Then, we divide the interval \( |t| \leq Cr_n \) analogously to Lemma 5 but with equidistance \( l_n \). The same notations related to this division are adopted here. Then, \( N_1 = C n^{\frac{3}{2} + \varepsilon_0} \). Clearly, we have that

\[
| \left( \Delta_n(b, s_n) - \Delta_n(a, t_n) \right) - \mathbb{E} \left( \Delta_n(b, s_n) - \Delta_n(a, t_n) \right) | \leq \sum_{i=1}^n (\xi_i + \mathbb{E} \xi_i),
\]

where

\[
\xi_i = K_{u,i} A_{u,i} I \left( \left| \xi_{a,i} - (a^T V_{u,i} + t_{i,n} - q_{\alpha,u} (X_{i,u})) \right| \leq l_n \right).
\]

Note that, for any \( s > 0 \), it holds that \( \mathbb{E} |\Delta_{i,2}(a, v_{j,n})|^s \leq C h_e r_n \). Then, by using Theorem 3 of Yoshihara (1978), Corollary 2.1 of Hall and Heyde (1980) and Rosenthal’s inequality, and taking \( m = n^{-6\varepsilon_0} (nh_e)^\frac{1}{2} \), and letting constant \( r > 0 \) sufficiently large, we know that

\[
N_2 \mathbb{P} \left\{ \bigcup_{t_n} \left\{ | \Delta_n(a, t_n) - \mathbb{E} \Delta_n(a, t_n) | \geq C \sqrt{nh_e n^{-\varepsilon_0}} \right\} \right\} \\
\leq N_2 \sum_{j=1}^{N_1} \mathbb{P} \left\{ \max_{1 \leq k \leq n} \sum_{i=1}^k (\Delta_i(a, v_{j,n}) - \mathbb{E} \Delta_i(a, v_{j,n})) \geq C \sqrt{nh_e n^{-\varepsilon_0}} \right\} \\
\leq N_2 \sum_{j=1}^{N_1} \left\{ C(r) \sum_{i=1}^m n^{\varepsilon_0} |\Delta_i(a, v_{j,n})|^r + \sum_{i=1}^n \mathbb{E} \left( \Delta_i^2(a, v_{j,n}) \right) \right\}^{\frac{r}{2}} + n \pi_m \\
\leq C N_1 N_2 \left\{ m \left( \frac{m^2 n^{11\varepsilon_0/2}}{C^2 \sqrt{nh_e}} \right)^{\frac{r}{2}} + n \pi_m \right\} \leq C \left( \frac{r}{n (\log n)^2} \right). \tag{S.21}
\]
Note that, for any $s > 0$, it holds that $\mathbb{E}|\xi_i|^s \leq Ch_e l_n$. On the other hand, by the same strategy and taking $m = n^{-3\varepsilon_0}(nh_e)^{1/4}$, it can be derived subsequently that

\[
N_2 \mathbb{P} \left\{ \bigcup_{i=1}^{n} \left( |\xi_i + \mathbb{E}\xi_i| \geq C\sqrt{nh_e n^{-\varepsilon_0}} \right) \right\} \\
\leq N_2 \mathbb{P} \left\{ \bigcup_{i=1}^{n} \left( |\xi_i - \mathbb{E}\xi_i| \geq \frac{C}{2} \sqrt{nh_e n^{-\varepsilon_0}} \right) \right\} \\
\leq N_2 \sum_{j=1}^{N_1} \left\{ C(r) \sum_{l=1}^{m} \frac{n(\mathbb{E}|\xi_i|^r + [\sum_{i=1}^{n} \mathbb{E}(\xi_i^2)]^{\frac{r}{2}})}{(C\sqrt{NH_e n^{-\varepsilon_0}}) + n\pi_m} \right\} \\
\leq C N_1 N_2 \left\{ m \left( \frac{m^2 n^{4\varepsilon_0}}{C\sqrt{nh_e}} \right)^{\frac{r}{2}} + n\pi_m \right\} \leq \frac{C}{n(\log n)^2}.
\]  
(S.22)

Then, from Borel-Cantelli Lemma, (S.21) and (S.22), we know that (S.20) holds. \hfill \square
